Abstract

Seasonal and diurnal patterns of 17 beta-hydroxyandrogens and testosterone in feral stallions are reviewed, and new data for two-year-old stallions with descended and undescended testes are presented. Previous work has demonstrated that mature feral stallions (three years or older) have a seasonal pattern of testosterone and total androgen secretion with peak levels occurring in May and a nadir from late September through December. As the blood levels of total androgens increased, the percent which was testosterone also increased. The seasonal pattern was similar to that of Quarter horses. Diurnal patterns indicated peak levels of testosterone at 0800 hrs and the nadir at 2300 hrs. An eight-year-old bachelor stallion which had demonstrated a consistent lack of libido had significantly lower testosterone levels ($P < 0.01$) than harem stallions, suggesting a relationship between plasma testosterone levels and reproductive behavior in feral stallions. The day-time blood levels of testosterone and total 17 beta-hydroxyandrogens were evaluated in two two-year-old stallions which had descended testes and had recently been driven from their respective bands. The same steroids were examined in 19 two-year-old stallions with undescended testes, all of which were permitted to remain with their harem bands. The two-year-old males with descended testes had testosterone concentrations of 1.9 and 4.8 ng/ml with a mean of 3.35 ng/ml, while the 19 two-year-old males with undescended testes had a mean testosterone concentration of 1.14 ± 0.23 ng/ml.

Presently there are an estimated 50,000 to 70,000 feral horses inhabiting the western United States. The herd size increases annually due to the protection afforded by the Wild and Free Roaming Horse and Burro Act of 1971 (P.L. 92-195) and inadequate means of population control. Reversible chemical fertility control, focused upon the stallion, is currently a possibility. The stallion is the target animal, rather than the mare, because of the harem band social structure. Such an approach requires a background study of basic reproductive physiology of the feral stallion.

OF THE
University of Wy
LARAMIE 86071

This paper reviews previous work regarding the plasma levels of 17-beta-hydroxyandrogens and testosterone in feral stallions, and the diurnal variations and seasonal changes of these steroids. Additionally, new data regarding plasma testosterone in feral stallions with descended and undescended testes are presented.

Methods and Materials

Diurnal Study: Four stallions from the Pryor Mountain Wild Horse Range in Montana were captured and confined to a corral several days before blood was collected. On the day of collection, the horses were restrained by halter ropes, to posts on opposite sides of each horse. This permitted the animals some movement but without danger of injuring themselves. The four animals were identified by name: Crooked Creek (CC); Welfare (W); Black (B); and Sorrel (S). These stallions were nine, eight, eight, and six years old respectively, and all were in good physical condition.

Beginning at 1600, 10 ml blood samples were collected hourly, by jugular venipuncture, in heparinized tubes, centrifuged, and the plasma immediately frozen on dry ice.

Seasonal Study: Thirty-four sexually mature (three years of older) stallions were captured on their home range in the Pryor Mountains, during September, October, December, March, May, and July. The animals were brought down by heading and heeling and blood samples were collected by jugular venipuncture. The heparinized blood samples were packed in ice and centrifuged within 24 hrs. of collection.

Immature Stallion Study: Nineteen two-year-old stallions with undescended testes were captured on the Pryor Mountain range. These sexually immature stallions were all permitted, by their respective harem stallions, to remain with their respective harem groups. Two additional two-year-old stallions were captured, which had descended testes and which had been recently driven from their harem groups. Blood samples were collected from all 21 animals as previously described.

Testosterone Assay: Total 17 beta-hydroxyandrogens were extracted from duplicate 0.5 ml plasma samples with three washes of diethyl ether, totalling 10 ml. The ether extracts were washed with two volumes of 0.1 N NaOH to remove estrogens. Testosterone (4-androsten-17 beta-ol-3-one) was separated from other 17 beta-hydroxyandrogens by Sephadex LH-20 column chromatography. The column was 6 mm (I.D.) X 31 cm and the solvent system was reagent grade heptane:chloroform: ethanol:water (50:50:1:saturation). Columns were prepared daily from a solvent-Sephadex slurry and eluted with 100 mls of solvent before use. The testosterone elution profile and percent recovery were established with ^{3}H-testosterone. One ml fractions 31 through 40 yielded 95 ± 2.8 percent (N=10) of the ^{3}H-testosterone.

Ether extracts of the plasma were dried and 1.0 ml of column solvent was added to each tube. Testosterone was collected in elutions 31 through 40, eluates were dried and 2 mls of ether were added and dried. Thin-layer chromatography was used to confirm results obtained with column chromatography. TLC was carried out with precoated silica gel plates (Van Waters Rogers) and petroleum ether:toluene (1:1 by volume) and 85 percent methanol. Identification was made with p-methoxybenzaldehyde (Kodak Chemicals).

Quantitation of plasma testosterone was accomplished by competitive-protein-binding assay described by Ganjam and Amann (1973). The protein-tracer-solution (PTS) consisted of 99.5 mls distilled water, 0.5 mls of third trimester human pregnancy plasma and (1,2,6,7-^{3}H) testosterone (New England Nuclear). The PTS was prepared fresh daily and stored at 5°C for at least one hour before use. The testosterone standard (Steraloids, Pawling, N.Y.) was recrystallized once and stored at 5°C in ethanol at a concentration of 10 ng/ml. Unbound steroid was removed by the addition of 40 mg Florisil (60/100 mesh) and shaking for two minutes. After 15 additional minutes of refrigeration, 0.5 mls of the PTS-testosterone complex was pipetted into 5 mls of toluene base scintillation cocktail (Liquiflor, New England Nuclear). This two-phase system was counted 24 hrs later in a Nuclear Chicago Model 720 LSC. Counting efficiency for tritium was 22 percent.

a) Recovery. Recovery of testosterone after extraction and column chromatography was 91.2 ± 3.7 percent (N=10) as determined by internal standard.
b) Precision. The coefficient of variation was 10.4 percent for 22 duplicate determinations carried out on different days. The inter-assay and intra-assay variation was 12.1 percent and 8.2 percent respectively.
c) Accuracy. Known amounts of testosterone standard (N=25) were assayed. Analysis of variance yielded a correlation coefficient of $r = 0.932$.
d) Specificity. The specificity of this assay is dependent upon the separation of testosterone from other 17 beta-hydroxyandrogens and estrogens (Vermeulin and Verdonck, 1970) and was evaluated by examining the constancy of testosterone standards after chromatography.
e) Sensitivity. Ten distilled water blanks gave an average value of 0.12 ± 0.09 ng/ml. The lowest value for measurable testosterone standards which differed from the blank value ($P < 0.05$) was 0.28 ng/ml.

Statistical Methods: Data were analyzed by analysis of variance and tested for significance with Duncans New Multiple Range Test (Alder and Roessler, 1972).

Results

Diurnal Variation: One of the horses, (S), never adjusted to the restraint and handling procedures. After the tenth hour of sampling this animal was released in order to prevent increased stress and probable death. As a result no data have been included for this horse. None of the remaining three horses showed undue stress; however, (W) remained somewhat aggressive throughout the study.

A definite diurnal variation in plasma testosterone was exhibited by all three stallions. The mean testosterone concentrations reached a nadir of 1.37 ±0.75 ng/ml plasma at 2300 and a peak of 3.48 ± 0.12 ng/ml plasma at 0800. The mean low concentration at 2300 differed significantly ($P < 0.01$) from those at 2300 to midnight and through 0400. The general pattern of testosterone levels indicated an increase beginning in the early morning hours. The testosterone concentrations more or less maintained a plateau during the daylight hours between 0800 and 1800.

sity of W
IE 86071

Of the three animals, the stud stallion Welfare had the highest mean testosterone concentration for the 24 hrs (3.2 ± 0.7 ng/ml). The stud stallion Crooked Creek had a 24-hr mean testosterone concentration of 2.7 ± 0.6 ng/ml. The bachelor stallion Black had a 24-hr mean testosterone concentration of 1.5 ± 0.9 ng/ml and differed significantly ($P < 0.01$) from both of the stud stallions. At both midnight and 0400 the bachelor stallion's testosterone concentrations were nondetectable (Kirkpatrick et al., 1976).

Seasonal Variation: A clear seasonal variation existed for plasma 17-beta-hydroxyandrogen and testosterone concentrations.

Since only two stallions were captured in September, these data did not lend themselves to statistical analysis and are therefore not considered here. The 17-beta-hydroxyandrogen nadir occurred in December (2.11 ± 0.39 ng/ml). Disregarding the two stallions in September, the testosterone nadir also occurred in December (1.55 ± 0.34 ng/ml) and the peak in May (3.04 ± 0.36 ng/ml).

When seasonal testosterone concentrations were examined as a percentage of the total androgens, the results were as follows: September=58%, October=67%, December=73%, March=81%, May=85%, and July=80%. As total 17-beta - hydroxyandrogen concentrations increased, the proportion which constituted testosterone increased dramatically (Kirkpatrick et al., 1977).

Immature Stallion Androgens: The testosterone levels for the twenty-one two-year-old stallions are shown in Figure I. The 19 two-year-old males with undescended testes had a mean testosterone concentration of 1.14 ± 0.23 ng/ml of plasma. The two two-year-olds with descended testes had concentrations of 1.9 and 4.8 ng/ml with a mean of 3.35 ng/ml.

Discussion

It is clear that in the three wild stallions examined a definite diurnal variation exists with regard to plasma testosterone. Diurnal testosterone variations have also been demonstrated in man (Faiman and Winter, 1971; Barberia and Cortes-Gallegos, 1973; Leymarie et al., 1974); the rat (Kinson and Liu, 1973); and the rhesus monkey (Goodman et al., 1974). Increased testosterone levels have been shown to occur in rams (Wetteman and Desjardins, 1973) during the dark hours. While not as clearly evident as in other species, the data of Katongole et al. (1971), imply a diurnal testosterone variation in bulls. In domestic horses, several investigators have noted diurnal variations of plasma testosterone (Ganjam and Kenney, 1974; Cox and Williams, 1975; Sharma, 1976).

The pattern of changes of plasma testosterone in the wild stallions is qualitatively similar to those seen in rats and man, with the nadir occurring between 1900 and midnight and the highest concentrations occurring between 0600 and noon, and differs from that of the rhesus monkey where highest concentrations occur at 2100. In several breeds of domestic horses, Ganjam and Kenney (1975) noted a diurnal variation of plasma testosterone, ranging from 4.2 ± 0.4 ng/ml at 0600 to 3.0 ± 0.3 ng/ml at 1800. These values are quantitatively similar to those found in the wild stallions. Cox and Williams (1975) examined diurnal variations of plasma testosterone in Welsh Pony stallions during April and June and noted irregular patterns of secretion.

The 24-hr mean testosterone concentration for the bachelor stallion (B) was significantly lower ($P < 0.01$) from the mean testosterone concentrations in the two stud stallions. Both the stud stallions have been successful in recent years, in gathering and maintaining a harem and both are assumed to have sired colts. The bachelor stallion, however, has not demonstrated even an effort to gather a harem. This is highly unusual for an eight-year-old wild stallion (Hall, 1972). Whether the significantly lower testosterone concentration represents a cause or an effect of such sexual disinterest is unanswered by this study.

When the mean testosterone concentrations of the wild stallions are compared with those of rats (Bartke et al., 1973); man (Faiman and Winter, 1971); the rhesus monkey (Goodman et al., 1974); the ram (Wetteman and Desjardins, 1973); and the bull (Katongole et al., 1971) they appear to be quite low. The wild stallion study reported here was conducted in late October, during the non-breeding season. It has been shown that in both wild stallions (Kirkpatrick et al., 1977) and domestic stallions (Berndtson et al., 1974; Raeside, 1978) testosterone concentrations fluctuate seasonally and are relatively low in October.

The 34 wild stallions examined in the seasonal study showed androgen and testosterone concentrations below 2 ng/ml during the three non-breeding months and above 2.38 ng/ml during the breeding months. Peak breeding activity occurred at the same time as peak androgen/testosterone concentrations. Increased aggressiveness between males also coincided with the higher concentrations. Berndston, Pickett,and Nett (1974) reported seasonal changes in testosterone in Quarter Horse stallions. These variations were similar to those in the 34 wild horses, with the nadir occurring in October and the peak in May. Although it is not reported in their study, it is assumed that nutritional levels remained fairly constant throughout the year. If that is the case, then nutrition must not be the predominant stimulus for androgen/testosterone fluctuations in the Quarter Horse. Nutrition is very poor during the winter months for the wild horse and the annual 'green-up' occurred at the same time androgen levels began to increase. A more recent study (Thompson et al., 1977) failed to confirm this seasonal pattern of androgens in domestic stallions, yet Raeside (1978) demonstrated seasonal testosterone patterns in domestic stallions which were similar to those seen in feral stallions. Whether nutrition plays any significant role in regulating androgen levels remains unanswered at present, but from the comparison of events in the wild and domestic horse, it appears improbable. The marked seasonal change in androgen/testosterone ratio indicates that testosterone becomes the predominant androgenic steroid during the breeding season. Exactly what the large proportion of non-testosterone androgens consists of during the non-breeding season is unknown and remains to be examined. All samples were collected between 800 and 1600 hrs. The diurnal study indicates fluctuations are very small during this period of the day, and it is improbable that diurnal variations caused erroneous results in the seasonal data.

Although the sample size of two horses, in the immature stallion study, precludes definite conclusions, there appears to be a dramatic increase in plasma testosterone near the time young stallions are ejected from their bands. This increase in testosterone results in plasma concentrations similar to those in mature harem stallions. Since we

ty of W
: 89071

have previously seen correlations between aggressive behavior and plasma testosterone concentrations, as well as seasonal behaviors associated with reproduction, it is reasonable to hypothesize that testosterone-induced behavioral changes, or testosterone-based pheromonal messages emanating from young stallions are ultimately responsible for their ejection from harem bands.

Sociosexual behavior and the ovulatory cycle of ponies (*Equus caballus*) observed in harem groups

Cheryl S. Asa [a], David A. Goldfoot *, O.J. Ginther [a]

Abstract

Observations of sociosexual behavior of adult ponies, made on two harem groups (each comprised of one vasectomized male and three females), were correlated with follicular development and ovulation for a total of 15 cycles (minimum of 2 cycles per female). Mean cycle length (interovulatory interval) was found to be 19.7 days, with behavioral estrus lasting 7–8 days (5.5 days preovulatory; 2.3 days postovulatory). Estrous females typically showed increased frequencies of approaching and following the stallion, urinating, presenting, clitoral winking, and tail raising. Approaching and following the stallion appeared earlier and persisted longer than other estrous responses. Deviations from the modal estrous pattern included cycles with subestrus, continual estrus, behavioral estrus in the absence of ovulation, and displays of female mounting. Dominance tests revealed that a mare's status was unaffected by the phases of the estrous cycle. The presence of more than one estrous female affected the copulatory performance of both stallions, most notably in reduced latencies to first mount, intromission, and ejaculation, in spite of differences between the stallions in sexual vigor. Each stallion usually selected the dominant mare for copulation when there were multiple estrous females present, but mounts were not displayed exclusively to one female per test. The social testing situation made apparent the importance of use of space in sociosexual communication in this species, particularly in avoidance of the stallion by diestrous mares and standing alone or in proximity to him by estrous mares.

Dexamethasone suppression of sexual behavior in the ovariectomized mare

Cheryl S Asa [a], David A Goldfoot *, M.C Garcia [a], O.J Ginther [a]

Abstract

The influence of steroids of adrenal cortical origin on estrous behavior in the ovariectomized mare was evaluated by adrenal suppression via dexamethasone (DEX) administration in two experiments. In Experiment I, 12 mares (six DEX, six control) were tested for sexual behavior in harem groups (two DEX and two control mares plus one stallion per group) for 9 consecutive days. In Experiment II, estradiol (E_2) was given to a group of DEX-treated mares as an additional control. Twelve mares (four DEX, four DEX + E_2, and four control) were tested in harem groups (one DEX, one DEX + E_2, and one control mare plus one stallion per group) for 10 days. All DEX mares showed a clear suppression of sexual response compared to control or DEX + E_2 mares, indicating that the estrous behavior seen in ovariectomized mares may be due to steroids from the adrenal cortex. The control and DEX + E_2 mares were similar in all measures of proceptivity. Despite being more receptive, as indicated by fewer negative responses, the DEX + E_2 mares received fewer intromissions and ejaculations than did the control animals. The ability of estradiol to induce estrous behavior in the dexamethasone-suppressed mare notwithstanding, other adrenal steroids, e.g., androgens, may be involved in estrous behavior in the untreated, ovariectomized mare.

HORMONES AND BEHAVIOR 14, 46–54 (1980)

Sexual Behavior in Ovariectomized and Seasonally Anovulatory Pony Mares (*Equus caballus*)

CHERYL S. ASA, DAVID A. GOLDFOOT,* M. C. GARCIA, AND O. J. GINTHER

*Department of Veterinary Science, University of Wisconsin, Madison, and *Wisconsin Regional Primate Research Center, Madison, Wisconsin 53706*

Ten ovariectomized (OVEX) and ten intact, but seasonally anovulatory (ANOV), pony mares were observed for sexual activity with five stallions, using a "harem group" social testing paradigm (two OVEX and two ANOV mares plus one stallion per group) for 15 consecutive daily tests lasting 20 min each. All mares in both conditions showed proceptive behavior in at least one test, all mares but one were mounted, and 14 of 20 mares received ejaculations. No statistical differences were found between the two conditions for any measure of proceptivity, copulatory activity, or days in estrus. The quality of estrus was judged to be equivalent to that displayed by periovulatory mares during their initial and terminal days of estrus, but less intense than that seen near ovulation. Mares in both groups were in estrus during approximately 60–70% of the tests and only 3 of the 20 mares were sexually refractory for more than five consecutive tests. Thus, the typical 2-week phase of sexual refractoriness seen in intact diestrous mares was absent in OVEX and ANOV mares, suggesting that the ovary plays a major role in actively suppressing estrous responses during the luteal phase of the cycle.

Steroids of gonadal origin have long been assumed necessary for the induction of estrous behavior in female mammals. Although Old World primates, such as the majority of rhesus and stumptail macaques, continue to show some copulatory behavior following ovariectomy (Goldfoot, Wiegand, and Scheffler, 1978; Baum, Everitt, Herbert, and Keverne, 1977), as is apparently also the case with a small percentage of rabbits (Yaschine, Mena, and Beyer, 1967), gonadectomized females of most mammalian species do not solicit coitus nor tolerate mount attempts unless administered exogenous steroids (Young, 1961; Goy and Goldfoot, 1975).

In this laboratory, estrous behavior has been noted in long-term ovariectomized mares (Garcia, published in Ginther, 1979). Estrous response has also been reported in mares whose ovaries were involuted during the nonbreeding season (Van Niekerk, 1967; Ginther, 1974; Webel, Franklin, Harland, and Dzuik, 1977). The present study was undertaken

to investigate in more detail the sexual response of mares in which ovarian hormones are absent (ovariectomized mares) or minimal (seasonally anovulatory mares).

METHODS

Subjects

Five stallions, 10 ovariectomized (OVEX) mares, and 10 seasonally anovulatory (ANOV) mares were used. The ponies were of apparent mixed breeding and weighed between 160 and 250 kg. The stallions ranged in age from approximately 3 to 20 years and the mares from 5 to 15 years. Four of the stallions were intact and one was vasectomized. The sexual experience of the mares before ovariectomy was not known. Gonadectomy was performed 6 months to 2 years before the present project. Rectal palpation revealed no evidence of ovarian fragments in any of the OVEX mares. After the completion of behavioral testing, an OVEX mare which had shown consistently high levels of estrous behavior was sacrificed and the entire reproductive tract removed after gross inspection of the body cavity. The tract was examined and the ovarian pedicles excised for histology.

In a previous study of intact, ovulating mares (Asa, Goldfoot, and Ginther, 1979), estrous behavior was never observed in mares with follicles of less than 15 mm diameter. Day (1940) reported that diestrus was accompanied by 10- to 15-mm follicles in pony mares. Therefore, the 10 ANOV mares were assigned to the project only after rectal palpation revealed small ovaries with follicles of no more than 10 mm diameter.

Mares were pastured together outdoors and provisioned with hay. Stallions were stabled separately and fed hay and grain.

Behavioral Testing

The study was conducted for 15 consecutive days from January 9 to 23, 1978. Behavior tests were given for 2 days before the study began to familiarize the animals with the testing situation. Five harem groups, each consisting of two OVEX mares, two ANOV mares, and one stallion, were assembled daily. Assignment of animals to harems was random each day with the exception that stallions were sometimes chosen to insure that each mare was tested with each stallion at least one time. Each harem group was observed daily for 20-min periods in the early afternoon. The outdoor paddock used for testing was approximately 6 by 9.6 m, with a straw-covered concrete base.

Behavioral data were taken on an SSR event-recording keyboard (Stephenson and Roberts, 1977) which allowed rapid notation of the incidence, latency, duration, and sequence of behaviors onto magnetic tape for subsequent computer analysis. Behaviors reported included approach, follow, urination, tail raise near stallion (TRNS), walk away,

mount, intromission, and ejaculation, which are defined elsewhere (Asa, Goldfoot, and Ginther, 1979). Kick, which was not defined previously, was scored only when both hind feet were used to strike out forcefully.

A behavioral index of estrus was developed in an earlier study in which all observations were made for 1-hr periods (Asa *et al.*, 1979). That index has been modified here for 20-min tests and expanded to allow quantitative analysis of the behavior of mares in conditions less vigorous than full estrus. For this study mares were considered in full estrus when they had more than two occurrences of urination and ≥20 sec of tail raise near the stallion (TRNS) during the 20-min test. The category of weak estrus included mares with one of the following: one occurrence of urination plus ≥20 sec TRNS, two or more urinations but no TRNS, or no urination but ≥60 sec TRNS per 20-min test.

Statistical Analysis

Comparison of the OVEX and ANOV groups for the display of various proceptive and receptive measures of the mares as well as for copulatory activity of the stallions was made by *t* tests for independent samples. A paired *t* test was used to evaluate the effect of weak or full estrous conditions on the frequency of kicks or walk-aways per mount.

To investigate the possibility of changes in the expression of estrus as the study progressed, the 15 days were divided into three 5-day segments. Analysis of variance for repeated measures (Winer, 1962) was used, with means for each mare for each 5-day period used as the three repetitions. The relationship between frequencies of urination (an indicator of proceptivity) and kicks and walk-aways per mount (indicators of nonreceptivity) was calculated using the Pearson product-moment correlation and the *t* test for significance of a correlation.

RESULTS

All mares in both groups showed proceptive estrous signs on at least one of the test days, although the intensity of estrus was sometimes low. Estrus determinations for the OVEX group ranged from one mare that was only in weak estrus in one test to another that was in full estrus for all 15 tests. The OVEX group means, as shown in Table 1, were 7.7 (± 1.75 SEM) tests with full estrus and 2.9 (± 0.74 SEM) tests with weak estrus for the 15 tests. The ANOV group means were 4.8 (± 1.45 SEM) tests with full estrus and 3.9 (± 0.98 SEM) tests with weak estrus. The ANOV group had one mare that was only in weak estrus for one test, but another that was in full estrus for 14 tests.

That mares in both groups were attractive and receptive to the stallions was demonstrated by male approaches and by precopulatory investigation and stimulation similar to that displayed to periovulatory estrous mares (Asa *et al.*, 1979), as well as by the complete male ejaculatory pattern. All

mares, except one in the ANOV group, were mounted at least once and all but four ANOV and two OVEX mares received ejaculations. Most of the ejaculations (94.8%) occurred with full estrous mares, 5.1% with mares in weak estrus, and none with mares judged not to be in estrus.

No differences were found between the two groups of mares on any of the 15 behavioral endpoints (Tables 1, 2). The means for the two groups for incidence of estrus and selected measures of proceptivity, attractiveness, and copulatory activity are shown in Tables 1 and 2. The mean frequencies for two forms of negative behavior, walking away during a mount (OVEX 1.2 ± 0.1, ANOV 1.2 ± 0.2) or kicking at any time during a test in which a mount occurred (OVEX 3.6 ± 1.8, ANOV 3.1 ± 0.5) were not different for the two groups of mares. The proportion of kicks and

walk-aways was no higher for weak estrus than for full estrus in either group. The mean number of kicks, but not walk-aways, per mount was negatively correlated with the mean frequency of urination, a measure of estrous intensity, for both groups (OVEX: $r = -0.359$, $P < 0.005$; ANOV: $r = -0.423$, $P < 0.005$).

Only one mare was consistently in estrus throughout the 15 days of the study. The others displayed an irregular pattern of full, weak, or no estrus from day to day (Fig. 1). Comparison of means for estrus and copulatory activity among the first, second, and third 5-day segments of the study yielded no differences. There was a mean of 1.58 (± 0.07) mares in full estrus and 1.18 (± 0.03) in weak estrus per harem group per test (out of four mares/harem group), with medians of two in full and one in weak estrus per test. The identity of those females in estrus in each test varied from day to day.

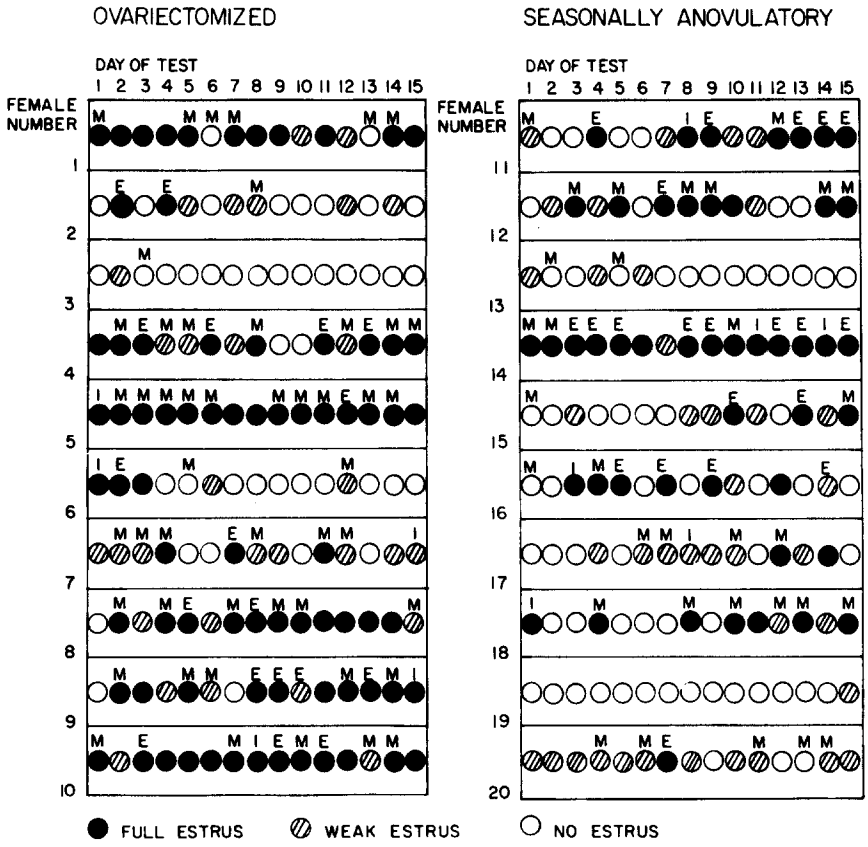

FIG. 1. Pattern of incidence of full, weak, or no estrus for 10 OVEX and 10 ANOV mares during 15 consecutive days of testing in harem groups. E, ejaculation; I, intromission; M, mount.

The five stallions displayed wide variability in copulatory performance, although mean number of mares in estrus per test was not different among stallions. In 15 days of testing, stallion 400 achieved only four ejaculations while stallion 100 had 12. The ratio of mounts per ejaculation was 3.25 for stallion 100, but 31.5 for the younger, less experienced stallion 200. The amount of time spent in precopulatory activity was reflected by latencies to first mount. These times ranged from a mean of 0.3 min for stallion 200 to 9.7 min for stallion 400. Stallion 100, the oldest, had the highest total number of ejaculations and the shortest latency to ejaculation while stallion 200, the youngest, had the most mounts and the longest ejaculation latency. For ejaculatory mounts, however, the mean interval from mount to ejaculation was not different among stallions.

Gross inspection of the body cavity and the reproductive tract of the sacrificed OVEX mare revealed no signs of ovarian-like tissue. Likewise, microscopic examination of the sectioned and stained ovarian pedicles disclosed no ovarian remnants or regrowth.

DISCUSSION

In this study both seasonally anovulatory mares and ovariectomized mares solicited copulation from stallions, were sexually attractive to them, and tolerated mounts, intromissions, and ejaculations. Such behavior in the pony under reduced hormone conditions is striking in light of the widely held belief that hormones of ovarian origin are exclusively responsible for displays of estrus in infraprimate mammals (Goy and Goldfoot, 1975; Leshner, 1978; Young, 1961). Nonetheless, it would be misleading to conclude that the pony is "gonadally emancipated," since the ovary is clearly involved in the regulation of estrous behavior during normal ovulatory cycles. Intact mares display very clear patterns of estrus for approximately 1 week out of every 3 throughout the spring and summer (Ginther, 1979). The week of behavioral estrus, with ovulation on about the fifth day, is followed by a period of marked sexual refractoriness during the 2-week diestrous phase, when mares respond to a stallion's approach and investigations with avoidance or threats (Asa *et al.*, 1979).

Comparisons of mares from this study to intact estrous and diestrous mares of a previous study suggest that the removal of the ovaries or the natural suppression of ovarian function during the winter months results in a chronic condition of moderate behavioral estrus, in which behavioral measures of attractivity, proceptivity, and receptivity are found with probabilities of at least 50% on any given test day. In contrast, estrus is seen on only about 33% of the days for intact mares during the ovulatory season (Asa *et al.*, 1979).

Proceptive components of estrus, such as the frequency of urinations, of following, or of standing near the stallion with the tail elevated were displayed with rates similar to those of intact mares during the initial and

terminal days of ovulatory estrus. Receptive elements of the response pattern were slightly reduced, however, in that proceptive OVEX and ANOV mares seemed to show more hard kicking and avoidance responses than intact estrous mares.

The intensity of estrus in ANOV and OVEX mares fluctuated in irregular patterns throughout the course of this study, perhaps due to the specific social composition of the groups formed on a given day, including individual preferences by mares for certain stallions, and dominance/subordination relationships among mares. Alternatively, these daily changes might have been related to changes of nonovarian-source steroids which could have been contributing to the phenomenon.

Only 3 of the 20 mares in this study displayed periods of sexual refractoriness for longer than 5 consecutive days, whereas half of the ponies never had more than a 2-day period in which estrous responses were not displayed. Thus, the absence of *cyclic* periods of nonreceptivity and nonproceptivity most accurately characterizes the behavioral changes following ovariectomy or seasonal ovarian quiescence in the mare. In contrast, a continual absence of estrous responses is typical of other ovariectomized or anovulatory infraprimate species.

These several observations and comparisons suggest the following three hypotheses. First, the luteal ovary appears to play a controlling role in the inhibition of estrous behavior, raising the possibility that progestational secretions of the corpus luteum provide the mechanism for periodic sexual inhibition during diestrus.

Second, although a nonhormonal mechanism might be responsible for estrous activity after ovariectomy, we hypothesize that the estrous behavior seen in this study was most likely supported by sex steroids, probably from the adrenals. Adrenal cortical mediation of sexual activity has been extensively considered in primate species (Everitt and Herbert, 1971; Everitt, Herbert, and Hamer, 1972; Goldfoot *et al.*, 1978; Baum, Slob, de Jong, and Westbroek, 1978). Hay and forage, which may contain phytoestrogens, present another potential source of steroids.

Third, since periovulatory estrus is more vigorous than that observed in OVEX and ANOV females, it is hypothesized that additional steroidal stimulation for these behavioral tendencies is supplied by the ovarian follicles in the days just prior to ovulation. Thus, it is likely that the follicular ovary of the mare, as in other species, increases the probability that copulation will occur during fertile phases of the cycle. However, the luteal ovary of the mare appears necessary to suppress estrus during the infertile phase of the cycle and therefore might be exhibiting a more potent inhibition of estrus than that thought to exist in most other infraprimate species (Feder, 1977).

The steroid condition resulting from ovariectomy represents an experimental manipulation which mares would normally never experience.

However, winter anestrus does occur naturally (Ginther, 1979), and 40–50% of mares in a typical free-ranging herd fail to deliver live young in a given season (Nelson, in press; Feist & McCullough, 1975). Thus, estrus might be displayed by some percentage of the nonpregnant, free-ranging mares during winter months.

The display of estrous behavior by mares at times during which conception is impossible might have functional significance to this species. The most commonly reported social unit of ponies and horses is of the harem type, with a stallion, several mares and their offspring (Feist and McCullough, 1976). Sexual activity outside of the breeding season, made possible by the absence of complete control of steroids from the ovaries over estrous behavior, could contribute to the maintenance of social bonds between the harem stallion and his mares. Further work directed to this possibility as well as toward the question of whether sex steroids from adrenal sources mediate these events is currently being investigated.

Abstract

Daily treatment (5 days) with estradiol resulted in increased levels ($p<0.05$) of proceptive behavior in ovariectomized as compared to control mares (N=8 per treatment) within 4 hr of injection and for the 4 subsequent days. Ejaculations occurred more often ($p<0.05$) in estrogen-treated mares on days 2–5, but the number of precopulatory investigations by the stallions was not altered. Progesterone treatment resulted in an absence of sexual behavior except in one mare on Day 1. Control mares exhibited varying levels of sexual interest. The concurrent administration of estradiol and progesterone produced a biphasic effect on proximity-related behaviors. Proximity behaviors were initially (Day 1) greater and subsequently less in the group treated with both hormones than in the group treated with estradiol alone. Injections of free estradiol resulted in a shorter latency to effect for two measures of proceptivity than did injections of estradiol benzoate. A dose response test for progesterone showed no effect with 0, 1, or 10 mg, but 100 mg was inhibitory ($p<0.05$). These results demonstrated that within 4 hr estradiol stimulated, while progesterone inhibited estrous behavior in ovariectomized mares and that concurrent administration of estradiol and progesterone produced a biphasic effect, first enhancing, then suppressing some aspects of the estrous response. The relatively short latency to action of all treatments and the biphasic effect of concurrent estradiol and progesterone may be attributable to low level, endogenous hormones.

Effect of stress induced by gathers and removals on reproductive success of feral horses

Michael C. Ashley and Dale W. Holcombe

Abstract Successful management of many species often relies on actions that involve intensive handling of individuals. Knowledge of how such handling may affect reproduction of a particular species is important and may be applicable to managing other species. We used pregnancy testing, field observation, Bureau of Land Management (BLM) records, and adopter surveys to determine effects of stress induced by gather and removal management practices on the reproductive success of feral horses in the Garfield Flat (GF) Herd Management Area (HMA) in Nevada. We analyzed pre-release confinement effect data from gathers conducted in August 1993 and January 1997 and data on the additional effect of removal in 1997. We used data for an ungathered population in the Granite Range HMA (GR) in Nevada as controls both years. Data from ungathered GR horses also were used as controls for habitat effects on reproduction. Granite Range and ungathered GF mares in 1997 had similar reproductive success rates (P=0.42). Pregnant removed mares in 1997 had less reproductive success than ungathered mares at GR (P=0.003) and GF (P=0.005). Gathered and released GF mares had less reproductive success than ungathered GF mares (P=0.05). The results suggest that minimizing time that mares are held prior to release will reduce fetal loss.

Key words abortion, horses, management, reproductive success, stress

In several studies, fetal loss in feral and domestic horses has been attributed to stress, often associated with frequent and extensive handling of pregnant mares (Mitchell 1971, Osborne 1975, Roberts 1986). Berger's (1983) study of feral horses in the wild found that forced copulation and social environment change after band takeovers in the Granite Range of Nevada caused abortions.

Most feral horse herds in the United States are managed intensively by the Bureau of Land Management (BLM, Boyles 1986). The Public Rangelands Improvement Act of 1978 authorized excess feral horse removal to preserve the quality of range habitat. Gathers and removals are the principal means to reduce populations to acceptable management levels (AML) for individual herd management areas (HMA; Boyles 1986). Each HMA is assessed by BLM range-condition specialists to determine stocking levels for livestock, feral horses, and game species. A 3- to 5-year interval between gathers and removals is necessary as many horse herds increase ≥20%/year (Wolfe 1980, Eberhardt et al. 1982, Berger 1986, Garrott and Taylor 1990). The removal magnitude depends on number of excess horses and the desired ending population size relative to the AML.

Gathers and removals may induce stress in several ways and for varying periods of time. Large-scale BLM gathers involve helicopter use to chase horses into a funnel trap leading to a corral. Trapped horses are individually restrained, aged, examined for physical

condition, and segregated for removal or release as adult and juvenile males, lactating mares and foals, and nonlactating mares. *Ad libitum* food and water is provided in corrals to minimize nutritional stress.

Horses released after a gather typically have been held for 2 to 4 days at the capture site. Horses removed for adoption face longer periods of stress. From the capture site horses are trucked to a processing facility, often hundreds of km away. Here they are again individually restrained for blood sampling, aging, and freeze-branding. Some adoption occurs locally; however, many more horses are transported to satellite adoption centers across the country. Horses can spend months in confinement before adoption. We investigated the role that stress plays in reproductive failure following gathers and removals. We feel that the results of this study are valuable to BLM management and are applicable to managing large-bodied ungulates in general, when translocations involve extensive handling or long periods of confinement.

Study sites

For >20 years, BLM has actively managed feral horses at the Garfield Flat (GF) and Granite Range (GR) HMAs in the Great Basin by conducting periodic gathers and removals to control population size. Both areas are subject to cattle grazing. The vegetation at both study areas is predominantly mixed grass and shrubs at lower elevations. At higher elevations, pinyon pine (*Pinus monophylla*) and western juniper (*Juniperus occidentalis*) predominate at GF. Western juniper also occurs at higher elevations at GR with stands of quaking aspen (*Populus tremuloides*) at some springs. The 607-km^2 GF HMA, located in Mineral County in west-central Nevada, is bordered on the east, north, and west by the Garfield Hills and on the south by the Excelsior Mountains. The playa at GF is 1,700 m above sea level (asl), with the Garfield Hills and Excelsior Mountains each rising above 2,400 m asl (United States Department of Interior 1985). Water is available year-round from 4 springs and ephemerally from 4 small catchments, ≤100 m^2 each (Figure 1). The 411-km^2 GR HMA is located in Washoe and Lander counties in northwest Nevada in the Granite

Range Mountains. Elevations range from 1,200 m asl in the surrounding lowlands to 2,735 m asl at Granite Peak (United States Department of Interior 1981). At this site, water is available year-round from numerous permanent springs and ephemeral ponds ranging from 50 to >400 m^2 in size.

Materials and methods

Gathers and removals

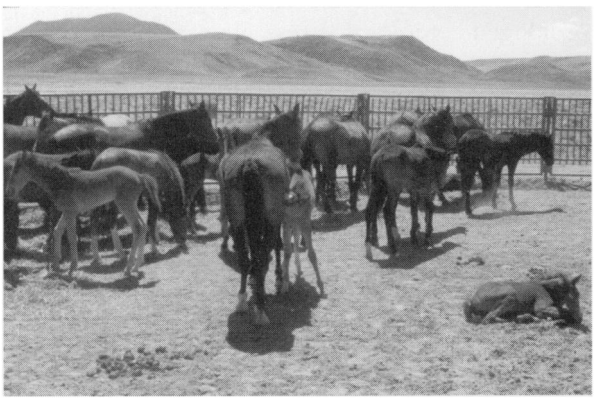
The first gather at GF was conducted in August 1993. The second occurred in January 1997. For both, a helicopter, drift fence, and funnel trap were used to capture horses. In the 1993 gather, resident horses in the eastern portion of the HMA were captured the first day and processed and released the second day. This procedure was repeated for horses in the western portion of the HMA on the following 2 days (Figure 1). Eighty-eight horses from the eastern area and 81 horses from the western area were captured, accounting for about 95% of the total HMA population. All horses gathered in 1993 were released except for 4 foals that were removed and one foal that was destroyed because of injuries. In 1997, horses were captured from the entire HMA over a 2-day period. Processing started immediately and continued for 2 days post-capture, culminating with the release of horses not shipped for adoption. The released horses were held 3 or 4 days, depending on capture order. Horses removed for adoption were trucked on days 3 and 4 to the Palomino Valley Center (PVC), a BLM adoption and processing center 246 km from the study site. Horses from the 1997 gather were examined and freeze-branded at PVC 2 weeks after the conclusion of the gather.

Horses appeared to be stressed at gathers, exhibiting agitated behavior. Confinement kept horses from different bands, groups of ≥1 adult female and any offspring attended by ≥1 adult male, at much closer quarters than we observed on the range. Mares too close to an unrelated foal were often threatened or kicked by the foal's mother. In contrast, we found that intra-band female–female aggression in the field was infrequent and limited to mild threats. Band spacing in the field generally precludes aggressive behavior. Inter-band aggression was usually observed between band stallions that often traveled >100 m to interact. Some bands were permanently disrupted after the release.

Tissue collection

In January 1997, we collected jugular blood samples at the gather site and at PVC in evacuated tubes from horses that would be ≥2 years old the following spring. We separated the serum component on site with a portable centrifuge (5,000 × g for 5 minutes) and stored the samples on ice for transport. We found that centrifugation at greater gravity than applied by Wolfe et al. (1989) efficiently separated the serum in less time. At the lab, we pipetted ≥1 ml serum/sample into individually labeled 1.5-ml microcentrifuge tubes and stored them at −80°C until samples could be assayed. Serum progesterone was determined using a solid phase radioimmunoassay kit (Coat-a-Count, kit #TKP6, Diagnostic Products Corporation, Los Angeles, Calif.; Wolfe et al. 1989). The coefficients of variation for progesterone were 8.1% for intra-assay and 9.7% for inter-assay results. Because nonpregnant mares generally do not cycle during the winter, we classified mares that had titers of ≥2 ng/ml serum progesterone as pregnant (Plotka et al. 1988).

Field methods



All released horses from both gathers at Garfield Flat were photographed and left-hip freeze-branded with unique numbers. Age (American Association of Equine Practitioners 1981), sex, and distinguishing marks were noted to aid in field identification. In February 1993 and November 1995 the BLM conducted gathers and removals at the GR HMA, releasing 359 and 123 freeze-branded horses, respectively. Identifying marks also were recorded for many of these horses.

We conducted intensive ground surveys of the GF and GR horses from March through August of

1994 and 1997 to assess reproductive success. Using 80-mm, 20X60-power spotting scopes, we identified horses by number and, when necessary, unique markings. To have reasonable confidence of accurately assessing reproductive success or failure, we only used data on mares that were sighted prior to, during, and after the prime foaling season, April to July. These sightings allowed us to assess whether an animal was visibly pregnant and whether a viable foal was produced. Mares classified as pregnant that were not accompanied by a foal by the end of August were scored as reproductive failures. We verified the foaling success or failure of all GF mares released after the 1997 gather. All successful pregnancies at both study sites were detected pre-partum in that surveyed mares seen with foals had been classified correctly as pregnant prior to foaling. Some of these mares at both sites were classified pregnant but were unaccompanied by foals at the end of the season. These reproductive failures of visibly pregnant mares may have included losses to mountain lions (*Puma concolor*) or coyotes (*Canis latrans*), even though we found no direct evidence of predation.

We assessed reproductive success for GR horses in 1994 and 1997 to serve as unmanipulated controls for the GF horses. The GR horses were gathered February 1993 and November 1995, early enough that there should have been no negative impacts on foaling in 1994 and 1997.

We collected GF removed mare reproductive success data in 1997 from BLM adoption records, adopter questionnaire, and telephone interviews with adopters. Unable to separate early foal death from fetal abortion in the field population, we included one stillborn, one death during birth, and the death after 1 day of a premature foal as evidence of reproductive failure for removed horses. In this tally, we also included 3 cases of pregnant removed mares that died prior to adoption. The BLM determined that the cause of these deaths was "poor condition" that could have been influenced by prolonged stress.

Segregated bands of lactating mares and foals at the 1993 gather.

Data analysis

Foaling success is a dichotomous event suitable for 2-by-2 contingency table analysis for pairwise comparisons. We used the 1-tailed Conditional Binomial Exact Test (CBET, Rice 1988) for these analyses, expecting that increased periods of stress would result in lesser foaling rates. This test is robust with moderate to small sample sizes and occasional small cell values.

The tests of differences in 1997 foaling success between gathered Garfield Flat mares and ungathered GR and GF mares are not equal comparisons, as the last 2 classes of mares were not tested for pregnancy. It is unlikely that all of the ungathered GR and GF mares assessed for foaling success were pregnant. Accordingly, this makes the comparisons of foaling success conservative tests.

Results

At GF, 45 (67.2%) of 67 marked mares foaled in 1994. These data represented all but 2 of the mares released in 1993 that would be ≥2 years old the following year. At GR, 20 (71.4%) of the 28 marked mares we surveyed foaled during the 1994 field season. Gathered and released GF mares had a foaling rate little different from GR mares (CBET: $P=0.43$). The minimum age of marked GR mares in 1994 was 4. Garfield Flat mares ≥4 years old ($n=34$) foaled at a greater rate (77.4%) than GR but did not differ significantly (CBET: $P=0.30$).

At the 1997 gather, released horses were held somewhat longer than in 1993, 3 to 4 days depending upon capture order. Removed horses were held ≥21 days before adoption. During the 14-day period prior to blood sampling at PVC, there were 15 to 18 spontaneous miscarriages as evidenced by shed fetuses (Sharon Kipping, PVC Manager, personal communication). One mare died that had a well-developed fetus *in utero*. Two pregnant mares died at interim locations before being adopted.

We pregnancy-tested 21 mares that were released at GF in 1997 and found 18 (85.7%) pregnant. Ten of these mares (55.6%) foaled. Of the mares removed in 1997 (66 tested, 1 autopsied), 43 (64.2%)

were pregnant. We verified the reproduction of 37 pregnant mares with only 17 (45.9%) producing viable foals. We also collected resighting data to determine reproductive success of 17 ungathered mares at GF in 1997. Fourteen (82.4%) produced foals. That same season we identified 54 mares at GR and found that 40 (74.1%) produced foals.

Two bands in the field, summer 1996.

At GF in 1997, stress duration for the 3 classes of mares was 0 days for ungathered ($n = 17$), 3.5 days for gathered and released ($n = 18$), and 21 days for removed mares ($n = 37$). Pairwise comparisons of the 3 classes of mares showed that pregnant mares exposed to longer periods of stress had lesser reproductive success. The greatest difference in reproductive success was between ungathered and removed mares (CBET: $P = 0.005$). There also was a significant difference between ungathered and released mares (CBET: $P = 0.05$). There was, however, no significant difference between released and removed mares (CBET: $P = 0.26$).

The reproductive rates of GR and the ungathered GF horses did not differ (CBET: $P = 0.42$). Granite Range horses had a greater reproductive rate than the pregnant released mares at GF, but the difference was not significant (CBET: $P = 0.08$). As expected, GR horses had greater reproductive success than pregnant mares removed from GF (CBET: $P = 0.003$).

Discussion

The effect of gather-and-removal-induced stress on pregnant feral horses is reduction in foaling success, sensitive to the duration of the stressor. The GF horses that were removed for adoption were transported long distances and subjected to repeated handling. Long-distance transportation has been linked to abortions in 2-year-old domestic mares (Roberts 1986). Mitchell (1971) and Osborne (1975) associated abortions in yearling and 2-year-old domestic mares with extensive handling. Generally, high pregnancy rates for yearlings and 2-year-olds followed by fetal losses have been reported for domestic (Mitchell and Allen 1975) and feral horses (Lucas et al. 1991). The reproductive losses for GF mares, however, were spread across age classes.

Stress, whether acute or chronic, stimulates the release of cortisol and other adrenocorticoids in mammals (Yates and Urquhart 1962). For example, in studies of gray squirrels (*Sciurus carolinensis*, Guthrie et al. 1967) and snowshoe hares (*Lepus americanus*, Boonstra et al.1998), trapping stress elevated serum corticosteroids. Snowshoe hares produced smaller litters during the decline phase of their 10-year cycles because of chronic stress imposed by elevated predation (Boonstra et al. 1998). Decline in serum progesterone has been linked to acute stress (van Niekerk and Morgenthal 1982). Serum progesterone is critical to pregnancy maintenance (Ball 1993). It likely is that severe and chronic reduction of serum progesterone due to prolonged removal stress was responsible for spontaneous abortions at PVC and overall decrease in reproductive success. An examination of serum cortisol and progesterone levels in response to gathers and removals would provide a definitive causal relationship between stress and reduced reproductive success.

Band takeover is another possible source of stress for feral mares. Berger (1983) reported instances of harassment and forced copulation in the Granite Range by stallions that had taken over bands. The stress of forced copulation coupled with changes in social structure caused induced abortions in mares

less than 6 months pregnant (Berger 1983). During our 6 seasons of field work, we observed many cases of harassment but only one forced copulation. The sole forced copulation was performed by a resident band stallion upon an unreceptive yearling mare. Most harassment incidents, however, were performed by bachelor males directed at harem mares. We saw no cases of harassment or forced copulation by stallions that acquired new bands. Further study is necessary to better evaluate the potential effects of forced copulation, harassment, and change in social structure on reproduction.

Removals from managed herds reduce the number of young horses ≤ 5 years old. Interestingly, this has the effect of temporarily increasing the proportion of the more reproductively successful horses in the population (Garrott et al. 1991). Seemingly, this works at cross purposes to desired population sizes at or below AML. To counter this effect, horses of all ages or a greater proportion of prime-age horses should be removed. Additionally, timing of removals can be exploited to extend the period of reduced population size. Gathers conducted in September or October, after the foaling season (Garrott et al. 1991), would reduce the next year's reproduction by interrupting early-stage pregnancies at a time when successful re-impregnation is unlikely. Feral horses are protected federally, and the BLM is charged with maintaining the general health and well-being of those horses under its jurisdiction (Boyles 1986). Such pregnancy disruptions would achieve a temporary reduction in population growth without large impacts on mare condition due to the small resource investment in early-stage fetuses.

Variation in the Short-Term Changes in Bone Cell Activity in Three Regions of the Distal Femur Immediately Following Ovariectomy

PAUL A.J. BALDOCK,[1,2] HOWARD A. MORRIS,[1,2] ALLAN G. NEED,[1] ROBERT J. MOORE,[3] and TIMOTHY C. DURBRIDGE[3]

ABSTRACT

The effect of ovariectomy (OVX) on cancellous bone in the rat is not uniform at all sites of the skeleton. We report variation in the short-term effects of adult OVX in three regions of the distal femur: the diaphysis (DIA), the metaphysis (META), and the epiphysis (EPI). Cancellous bone parameters were estimated in the three separate zones of the femora and compared with changes in bone cell activity, as estimated by osteoclast surface (Oc.S) and bone formation rate (BFR). Changes were studied for 30 days in a series of rats either sham-operated (Sham) or ovariectomized (OVX) at 7 months of age. Oc.S and BFR were elevated following OVX in all regions. The time course for the OVX-induced changes differed between regions: DIA, both Oc.S and BFR were elevated at day 9; META, Oc.S was also elevated at day 9, while the rise in BFR was delayed until day 21; EPI, Oc.S remained stable but increased relative to ovary-intact rats by day 18 due to reduced levels in the latter, but BFR did not rise until day 28. These changes in bone cell activity following OVX produced a 71% reduction of cancellous bone in the DIA and a 35% reduction in the META. In contrast, no OVX-induced bone loss was observed in the EPI. This study shows that bone cell activity increases in each region of the distal femur within the first 30 days following OVX, independent of bone loss. However, the time course of increased bone cell activity is not uniform. These data highlight the role of local factors in the response to ovarian hormone deficiency. (J Bone Miner Res 1998;13:1451–1457)

INTRODUCTION

Bone loss resulting from estrogen deficiency in the rat consists predominantly of cancellous bone loss[1] through a mechanism that involves elevated turnover.[2,3] In the rat distal femoral diaphysis (DIA) and proximal tibia, bone resorption increases at ~6 days postovariectomy (post-OVX), while formation is not increased until 9–12 days, and cancellous perforation is detected by 12–15 days postoperation.[2,3] The bone loss at these sites does not result from a generalized thinning of all trabeculae but by perforation and removal of the entire trabeculae.

A similar mechanism of perforation is proposed for both postmenopausal osteoporosis[4] and OVX-induced bone loss.[5,6] However, the rate and magnitude of bone loss varies within the skeleton in all species studied. The factors responsible for such selective loss are not understood. Possibly mechanical strain, exerted locally within each individual trabecula, may play a role in determining survival, with the lesser strained units being removed first.[7] This theory is supported by the preferential loss of horizontal trabeculae in human vertebral bodies[8] and the disruption of the pattern of OVX-induced bone loss in the tibia of the rat when performed in concert with hemicordectomy.[9]

It has been reported that the extent of bone loss varies between neighboring regions within a single bone. Bone mineral density of the femoral epiphysis (EPI) in the rat did not decrease in a 26-week period following OVX at 4, 10, or

52 weeks of age, despite significant decline in the distal metaphysis (META) during this period in all three groups.[10] Westerlind et al.[11] reported that OVX in the rat decreased the cancellous bone volume (BV/TV) in the femoral META by 75% after 11.5 months, while the EPI remained unchanged, despite a 220% increase in eroded perimeter and a 440% increase in the fluorochrome-labeled perimeter in the latter region.[11] This heterogeneity has also been alluded to by others[12–14] and suggests the existence of large variations in the susceptibility of cancellous bone to ovarian hormone deficiency. However, it is unknown whether activation of bone cells with ovarian hormone deficiency occurs simultaneously in all regions or whether there is a delay in those regions that are apparently resistant to ovarian hormone-deficient bone loss.

We now report the cellular and morphologic events occurring in the EPI during a period of accelerated turnover and bone loss in the DIA of the distal femur. The study samples three separate regions of the rat distal femur for 30 days following OVX. Static and dynamic histomorphometric techniques are used to examine the effect of estrogen deficiency on the morphology of the cancellous bone as well as resorption and formation variables.

MATERIALS AND METHODS

Animals

Ninety female 6-month-old Sprague-Dawley rats were obtained from the Gilles Plains Animal Resource Center (Gilles Plains, South Australia). Rats were housed at 22°C on a 12 h light/dark cycle in standard cages housing groups of six animals and were supplied with commercial rat chow containing 0.76% calcium, 0.46% available phosphorus, and 2000 IU/kg of vitamin D_3 (Milling Industries, Murray Bridge, South Australia) and tap water ad libitum. All procedures involving the animals were approved by the Institute of Medical and Veterinary Science Animal Ethics Committee.

Surgery

At 7 months of age, six animals were killed as a baseline group and the remainder allocated to either OVX or sham operation (Sham), both performed under halothane anesthesia. All rats received demeclocycline (Lederle, Sydney, Australia) 30 mg/kg of body weight and calcein (Sigma Chemical Co., St. Louis, MO, U.S.A.) 20 mg/kg of body weight by intraperitoneal injection, 6 and 2 days, respectively, prior to killing. At 9, 15, 18, 21, 24, 28, and 30 days postoperation, six OVX and six Sham rats were weighed and killed by cervical dislocation under halothane anesthesia, and the right femora were excised.

Tissue preparation

The distal 20 mm of each femur was bisected in the sagittal plane. Cutting and trimming were performed using a low-speed saw (Buehler Ltd., Evanston, IL, U.S.A.), with a diamond-tipped cutting blade. Bone samples were fixed in 10% neutral buffered formalin for 4 h, dehydrated in graded ethanol (70%, 90%, 2× 100%) for 1 h each, then transferred into two changes of methyl methacrylate (BDH, Poole, U.K.) containing 8% v/v K-Plast Plasticizer (Medim, Giessen, Germany) for 3 days. All processing was conducted at 4°C. The samples were polymerized in a 37°C waterbath in sealed polypropylene tubes using 4 ml of methyl methacrylate containing 8% v/v K-Plast Plasticizer and 0.9% w/v K-Plast initiator for 16 h. Five-micrometer-thick longitudinal sections were cut using a Jüng K motorized microtome (Reichert, Heidelberg, Germany).

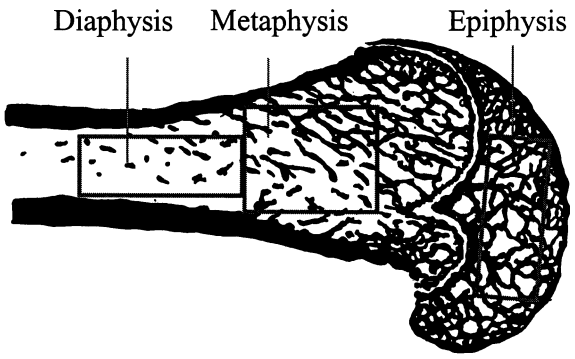

FIG. 1. Longitudinal section of distal femur showing margins for sampling.

Histomorphometry

The percentage of marrow cavity occupied by mineralized bone and its surface length were measured in 5 μm sections stained by a modified von Kossa silver technique.[15] Sections were partitioned into three regions (Fig. 1): the epiphyseal region below the growth plate; the metaphyseal region extending from 3 mm above the most distal point of the growth plate, excluding primary spongiosa from analysis, to 7 mm above the growth plate; and the diaphyseal region from 7–12 mm above the growth plate. The mean sampling area (mean ± SEM) was 14.4 ± 0.3 mm^2 in the DIA, 9.2 ± 0.2 mm^2 in the META, and 10.3 ± 02 mm^2 in the EPI. An Olympus BH-2 microscope (Olympus, Tokyo, Japan) interfaced with a Quantimet 520 Image Analysis System (Cambridge Instruments, Cambridge, U.K.) was used for all measurements. BV/TV, trabecular number (Tb.N), and trabecular thickness (Tb.Th) were calculated from the percentage area and surface data.[16]

Dynamic markers of bone turnover were measured in all three regions. Extent of the double fluorochrome labeled surface as a percentage of total surface (dLS) was determined manually on unstained 5-μm-thick sections using a Zeiss fluorescence microscope (Zeiss, Jena, Germany) with an ocular mounted Weibel II graticule (Graticules Ltd., Tonbridge, U.K.) at ×250 magnification. The interlabel distance was measured at multiple sites along the labeled surface using an ocular mounted micrometer at ×400 magnification. The mineral apposition rate (MAR) was calculated by dividing the interlabel distance by the time interval

Values are mean (SEM) for cancellous bone volume (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), osteoclast surface (Oc.S), and bone formation rate (BFR) measured in the diaphyseal region of the distal femur in nonoperated rats (0 days), sham-operated (sham), and ovariectomized rats (OVX) at 9, 15, 18, 21, 24, 28, and 30 days postoperation at 7 months of age.

* Significant change with time ($p < 0.01$). † Significantly different to sham with time ($p < 0.05$). ‡ Significantly different to sham ($p < 0.05$).

between labels (4 days). The percentage of cancellous surface covered by osteoclast-like cells was estimated manually using an ocular mounted Weibel II graticule for 5-μm sections stained with a modified von Kossa silver technique followed by a hematoxylin and eosin counterstain (VK/HE) at $\times$200 magnification. Osteoclast surface (Oc.S) was estimated using the VK/HE sections. Osteoclasts were identified as cells with multinucleate, round speckled nuclei, and foamy eosinophilic cytoplasm adjacent to cancellous bone surfaces, except those covered with osteoid. In both dLS and osteoclast estimates, contiguous fields were counted to include all cancellous bone in each region. Single sections were examined for each parameter, and analytical variance was not assessed.

Calculations and statistics

The bone formation rate (BFR; tissue level, total surface referent) was calculated as the product of MAR and dLS. Intraregion analysis was conducted using repeated measures analysis of variance with contrast to compare the mean values for each variable for the two operative groups at each time point. Change through time was estimated by regression analysis assessed for each group and compared with the corresponding operative group in that region. Inter-region analysis was conducted by analysis of variance with contrast on the slopes of the regression equations of time on the difference between the individual OVX values and the mean of the Sham value for each time point. Due to the difference in baseline values between regions, structural cancellous bone variables were normalized by expressing the resultant individual OVX values as a percentage of the mean Sham value for that time point and region. This design of the statistical examination included a correction for multiple analyses. Statistics were performed using PC-SAS (SAS Institute, Cary, NC, U.S.A.) with $p < 0.05$ considered significant.

RESULTS

Completeness of OVX was confirmed at death in all OVX rats by the absence of ovarian tissue and atrophied uterine horns. Body weight (mean $\pm$ SEM) was not greater in OVX animals compared with ovary-intact animals, 324 $\pm$ 4.5 g and 318 $\pm$ 2.9 g, respectively.

Intraregion comparison

In the DIA (Table 1), BV/TV fell in both groups (Sham, $p < 0.005$; OVX, $p < 0.0001$), with a greater loss in the OVX group ($p < 0.05$), decreasing to 29% of the Sham level at day 30. There was a decrease in both Tb.N and Tb.Th in both groups, which was greatest at day 15. Tb.N was decreased in the OVX group compared with Sham by day 21, and Tb.Th was decreased by day 28. Oc.S was not altered in the Sham group but there was an increase in the OVX group ($p < 0.005$), which was detectable at the first time point, day 9. BFR did not change in the Sham group throughout the period. In the OVX group, it was increased compared with Sham at day 9 ($p < 0.0001$).

In the META (Table 2), BV/TV also fell in both groups (Sham, $p < 0.01$; OVX, $p < 0.0001$). Again the bone loss was greater in the OVX group with the OVX value 65% of

Values are mean (SEM) for cancellous bone volume (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), osteoclast surface (Oc.S), and bone formation rate (BFR) measured in the metaphyseal region of the distal femur in nonoperated rats (0 days), sham-operated (Sham), and ovariectomized rats (OVX) at 9, 15, 18, 21, 24, 28, and 30 days postoperation at 7 months of age. *Significant change with time ($p < 0.01$). † Significantly different to sham with time ($p < 0.0001$). ‡ Significantly different to sham ($p < 0.05$).

the Sham values at day 15. BV/TV fell as a result of a decrease in Tb.Th in the Sham group, whereas in the OVX group it was due to both decreased Tb.Th and Tb.N. Tb.N was decreased in the OVX group compared with Sham by day 15 and reduced only at day 28. Oc.S increased in the OVX group while it decreased in the Sham group ($p < 0.005$), resulting in significantly greater levels in the OVX group ($p < 0.0001$) at the first time point, day 9. BFR increased in both groups (Sham, $p < 0.005$; OVX, $p < 0.0001$). The rise was greater in the OVX group ($p < 0.0001$) by day 21.

In the EPI (Table 3), BV/TV also fell in both groups (Sham, $p < 0.001$; OVX, $p < 0.0001$) to 85% of baseline values at 30 days. However, there was no difference between operative groups. The reduction in BV/TV was due solely to a reduction in Tb.Th. Tb.N was stable in the Sham group and tended to increase in the OVX group ($p < 0.01$). There was no OVX-induced rise in Oc.S in this region. However, a significant decrease in the Sham group ($p < 0.001$) resulted in relatively greater Oc.S in the OVX group ($p < 0.0001$) delayed until day 18. BFR increased in both groups (Sham, $p < 0.005$; OVX, $p < 0.0001$), and the rise was greater in the OVX group ($p < 0.005$) delayed until day 28. Changes in BFR were primarily due to changes in dLS, because MAR rose only in the META (Sham, $p < 0.05$; OVX, $p < 0.001$) and Sham EPI ($p < 0.05$) (data not shown).

Inter-region comparison

The OVX-induced decrease in BV/TV in the DIA was significantly greater than in the EPI ($F = 7.21$, $p < 0.01$). There was also a trend for bone loss to be greater in the META compared with the EPI ($F = 3.12$, $p < 0.08$). There was no difference between loss of BV/TV in the DIA and the META. Tb.N was significantly reduced in the DIA ($F = 5.81$, $p < 0.05$) and META ($F = 5.96$, $p < 0.05$) compared with the EPI. There was also a trend for a greater reduction in the DIA compared with the META ($F = 3.16$, $p < 0.08$). Tb.Th was significantly reduced in the DIA compared with the META ($F = 4.15$, $p < 0.05$). The time for the response of Oc.S to OVX in the DIA was less than for both the META ($F = 7.09$, $p < 0.01$) and the EPI ($F = 4.63$, $p < 0.05$). There was no significant difference between the META and EPI (Fig. 2A). The time for the response of BFR to OVX was significantly less in the DIA than for both the META ($F = 6.02$, $p < 0.05$) and the EPI ($F = 5.93$, $p < 0.05$), while the META was significantly less than for the EPI ($F = 5.55$, $p < 0.05$) (Fig. 2B).

DISCUSSION

This study has identified variations in the short-term response to systemic ovarian hormone deficiency in three regions of the rat distal femur, and the extent of variation in response to ovarian hormone deficiency has been quantitated. Thirty days of ovarian hormone deficiency produced a reduced BV/TV compared with ovary-intact animals of 71% in the DIA, but only 35% in the META, while the EPI showed no decline. Bone cell activity increased in all regions, although the time course of this increase was not uniform between regions and was independent of bone loss. The response of appendicular cancellous bone to the sys-

temic loss of estrogen has generally been studied using single sample areas only or regions from disparate parts of the skeleton.[13,14] Such variations within a single bone suggest the importance of local factors in the mediation of this process.

In a study of the short-term effects following OVX, the impact of a remodeling transient must be considered.[17] Estrogen deficiency triggers a change in activation frequency and thus there is a period when resorption exceeds formation purely due to increased recruitment of osteoclasts. The true steady-state alteration to bone balance cannot be assessed until at least the end of the first remodeling period. This has been estimated in rat caudal vertebrae to last for 38 days.[18] The rapid nature of bone loss in this study highlights the impact of a remodeling transient in the META and DIA, and further suggests that bone cell activity increased prior to the initial time point 9 days after operation. This finding is in keeping with previous studies.[2,3]

Following OVX, Tb.N was reduced in the META by 25% and in the DIA by 50%, displaying the pattern typical of estrogen-deficient bone loss reported previously.[2,3,9,12–14,19–21] These reductions were significant when compared with the EPI, which showed no reduction in Tb.N. The absence of a reduction in Tb.N in the epiphyseal region of OVX groups is atypical for cancellous bone, and the mechanism behind the immunity of epiphyseal trabeculae to dissolution remains elusive. The most compelling explanation is the influence of mechanical strain.[3,12] External mechanical loading has been shown to inhibit resorption,[22] a finding consistent with the lack of an absolute increase in resorption in the EPI following OVX. Other explanations include baseline levels of turnover[14] and osteoprogenitor cell populations as possible factors.[12] However, structural differences between the regions may also be involved. In a steady state, increases in bone turnover are unable to produce permanent alterations to BV/TV.[23,24] Computer modeling has shown that a doubling of activation frequency causes transient, mainly reversible, bone loss, but when accompanied by an increase in resorption depth, the irreversible component is more pronounced.[25–27] Epiphyseal trabeculae are thicker than in the other regions, making perforation less likely.

Following OVX, resorption was elevated in all regions. The time course for these changes, however, was not uniform. In the DIA and META, Oc.S was increased at day 9 post-OVX, while in the EPI the Oc.S did not rise at all but showed a relative increase by day 18. The increase in Oc.S following OVX relative to ovary-intact groups was greater in the DIA than in the other two regions. The BFR was increased in the DIA at day 9. In the META, the increase was delayed with BFR not exceeding ovary-intact levels until day 21. In the EPI, the increase was further delayed until day 28. These differences in response were significant among all three regions. Such findings are in keeping with differences in the time course of increased turnover between the proximal tibial META[21] and the first lumbar vertebrae,[14] with a more rapid response occurring in the tibia. Thus, factors local to particular regions must alter the time course of alterations to bone turnover subsequent to estrogen deficiency. This is the first time that variation in the time course of response to estrogen deficiency has been reported in neighboring anatomical regions within a single bone.

In contrast to previous studies,[2,3] a decrease in Tb.Th in each area, independent of estrogen status, was observed associated with decreased Oc.S and increased BFR over the 30 days. In 7-month-old rats, the longitudinal growth rate is reduced to 0.12 mm/month or 0.3% of the total femoral length.[28] Age-related loss of BV/TV is limited to ~1.2% per month in the DIA and 0.3% per month in the META and EPI. Thus, it is possible that the decrease in Tb.Th is the result of a temporary disturbance due to the operations. The long-term study of these areas would determine whether these changes are sustained.

The data presented here display the extent to which cancellous bone loss due to estrogen deficiency is modulated by local factors. The time course of increased bone turnover was different in all regions, being more rapid proximally. The exact mechanism involved in the epiphyseal immunity to bone loss is uncertain. However, the speed at which estrogen deficiency induces bone loss suggests that increased resorption depth is likely to be an important factor.

An Economic Analysis of Alternative Fertility Control and Associated Management Techniques for the Pryor Mountain Wild Horse Herd

John M. Bartholow
U.S. Geological Survey
Fort Collins Science Center
2150 Centre Avenue, Bldg. C
Fort Collins, CO 80526-8118

July 7, 2004

Executive Summary

Contemporary cost projections were computed for several alternative strategies that could be used by BLM to manage the well-studied Pryor Mountain wild horse population. The alternatives included (1) existing contraceptive, gather and selective removal methods; (2) different contraceptive techniques offering effectiveness of greater duration; (3) manipulation of herd sex ratio; and (4) a gather and removal-only scenario. Costs were projected for a 20-year economic life using the Jenkins wild horse population model and cost estimates from BLM that reflect this herd's specific removal, adoption, and contraceptive application expenses. Important findings include:

- The Pryor Mountain herd has a low intrinsic growth rate that tends to moderate wide inter-annual population fluctuations and greatly minimizes cost differences among contraceptive scenarios.
- All contraceptive scenarios have roughly equal costs compared with exclusive gather and removal management without contraceptive application.
- Treatment with contraceptives under the existing application protocol is predicted to be approximately 50% less costly than gather and removal management alone.
- Annual application via darting is cost-effective on this herd compared with more "conventional" contraceptive applications every 4 years even if the contraceptives have a long (3-year) duration. However, the longer-acting contraceptives reduce the expected inter-annual variability in average expenses.
- The Alternative Baseline scenario is predicted to be the least expensive option, but the consistent treatment of all older aged mares called for in this scenario is unlikely to be sustainable over a 20-year period without reducing the population below desired AML levels.
- Average annual costs would decline slightly if the herd's sex ratio were adjusted to leave more males on the range, but care must be used not to remove too many mares of prime foaling age lest the population decline below desired levels.
- In general, cost estimates are most sensitive to annual monitoring expenses, not to direct contraceptive or removal/adoption costs.
- The 4-year gather cycle is appropriate for this herd, though costs are not very sensitive to the gather frequency.

Introduction and Objective

This report is an addendum to a previous economic analysis conducted by USGS for BLM that examined contraceptive and management options for three wild horse populations (Bartholow 2004). The sole focus of this current report is the Pryor Mountain wild horse herd, which has previously been subject to contraceptive treatment. Management flexibility is, however, important, and treatment regimes may change through time. The current report examines some potential management alternatives in a manner that is generally parallel to, but not identical with, Bartholow (2004).

The BLM's goal for the Pryor Mountain herd is management at a clearly established appropriate management level (AML) at minimum cost. Alternative means to achieve this goal are explored in this report and include: (1) the status quo of annual contraceptive application, selective removal and adoption; (2) the frequency of gathers and how efficient they are in rounding up animals; (3) status quo plus several alternative contraceptive application scenarios, specifically the duration of the contraceptive agent and using contraceptives annually or in concert with a 4-year gather cycle; and (4) other potential management techniques, such as sex ratio manipulation through age- and sex-specific removal decisions.

Study Area

The Pryor Mountain Wild Horse Range was established in 1968 and occupies 38,000 acres of multi-jurisdictional lands along the border of Montana and Wyoming, about 13 miles north of Lovell, Wyoming. This mostly arid Range supports about 100-200 wild horses in a largely free-roaming condition. Harsh winters and abundant predators may help limit the number of older animals (with few >16 years old) and contribute to variable, and intermittently high, foal mortality. Conflicting management perspectives stimulated research on several issues germane to proper management of this population, including vegetation dynamics and population genetics (Singer and Schoenecker 2000).

Fertility control research began on the Pryor Mountain herd in 2001 and continued in 2002 and 2003. Contraceptives have been applied using remote darting techniques not necessarily associated with regular gathers. Darting uses an initial primer and annual booster, and can take place over a period of time, reaching 100% of the mares targeted for the contraceptive program. BLM currently envisions giving the contraceptive agent porcine zona pellucida (PZP) vaccinations to all yearling and 2-year-old mares and those 14 years and older, allowing younger mares to mature in a healthy state prior to the rigors of pregnancy and allowing older mares to live their senior years in better overall health. This protocol, termed “compassionate-use” fertility control, is envisioned to improve mare health, reduce foal loss, and help prevent orphaned foals.

Additional information concerning this herd is available from BLM (USBLM 2004).

Methods

Step 1. Define Baseline and Specific Alternatives

This analysis examines the following scenarios:

- Baseline Scenario – Existing "baseline" conditions as reflected in current management policy (USBLM 2004). This is a regular 3-4 year gather with age-specific removal rates, specifically 50% for age classes 1, 2 and 3, and 25% of 4-year olds. It is assumed that 100% of horses removed are targeted for the adoption pool, and are held an average of 30 days prior to adoption. Removals are assumed never to end up in long-term holding facilities.

  "Compassionate-use" fertility control involves 100% treatment for yearling and 2-year old mares, and also for mares 14 years and older. Under the baseline scenario, contraceptives are applied via annual darting and do not require gathering.

  Unfortunately, existing management of the Pryor Mountain herd can only be approximated by the current Jenkins model. The limitation arises because the model does not allow for dual management (contraceptives and removals) on two different frequencies (annual and 4-year) at two different efficiencies (100% for contraceptive darting and only 70% for gathers). Further, the cost estimation program does not allow differing costs for contraceptive application that might occur in conjunction with a 4-year gather as opposed to annual darting. In order to approximate existing management, I ran the Jenkins model on a 1-year gather cycle, but removed animals at one-fourth the removal rate that would have occurred if it had been a 4-year gather Actually, I used a rate of 0.175 [0.7 x 0.25] to account for the normal gather efficiency of 70% (Table 1). This technique is not a completely faithful representation for all the reasons mentioned, but it should reasonably approximate baseline costs.

  Table 1. Comparison of removal rates for annual darting scenarios and conventional 4-year gather cycle. Rates for annual darting scenario are 0.175 times the rates for the regular gather scenarios, but must be rounded to the nearest whole percentage for the Jenkins model.

Age class	Regular 4-year gather scenarios	Annual darting scenarios
0	0	0
1-3	50	9
4	25	4

  One other model adaptation concerned handling removal rates for 14-year old horses. The Jenkins model lumps older animals into ages 10-14, 15-19, and 20+. I approximated removal of older animals by spreading applicable rates among the age classes, with values derived from Linda Coates-Markle.

  Efficacy rates for dart-delivered contraceptives are shown in Table 2, along with rates for more conventional contraceptives, discussed below.

- Alternative Baseline – Modification of the Baseline Scenario being considered for the Pryor Mountain herd. This alternative is identical to the Baseline scenario except that it also treats 50% of all other age classes (3-13) with contraceptives.

- Conventional Contraceptive Scenarios – These scenarios are meant to represent contraceptive strategies being used, or anticipated, on many other BLM-managed wild horse herds (USBLM 2002), and are similar to those investigated by Bartholow (2004). Instead of the annual darting, contraceptives would be applied solely in conjunction with a regular 4-year gather cycle, and nominally represent either 2- or 3-year duration, defined more precisely with percent effectiveness in the first and subsequent years as shown in Table 2.

  Contraceptives are assumed to be applied to all mares returned to the range. Note that it is considered to be the case, and the Jenkins model assumes, that if the vaccine does not produce infertility in the first year for a given mare, it would never be effective in subsequent years until re-treatment. The 1-year scenario values also given in Table 2 represent values found with annual darting on the Pryor Mountain herd and used in conjunction with the Baseline scenarios, while the 2-year scenario values represents values from a recent assessment of a different herd.

  Table 2. Annual effectiveness of existing and potential contraceptive treatments. These are gross efficacy rates that are further tempered by age-specific fertility rates in the Jenkins model. Values for 1- and 2-year treatments confirmed by Linda Coates-Markle. Values for 3-year agent were liberally extrapolated from 2-year efficacy rates. One-year contraceptives represent the effectiveness achieved through darting (primer and booster).

Nominal Duration	Effectiveness Year 1 (%)	Effectiveness Year 2 (%)	Effectiveness Year 3 (%)	Effectiveness Year 4 (%)	Effectiveness Year 5 (%)
1-year	90	0	0	0	0
2-year	94	82	68	0	0
3-year	94	82	68	33[1]	0

[1] Since running these simulations, newly collected data are available for the Clan Alpine herd (J.W. Turner, Jr., technical notes on Clan Alpine HMA Wild Horse Survey, June 2004, supplied by Linda Coates-Markle). These notes do not support 4th year effectiveness. Therefore, the cost estimates for scenarios involving the 3-year contraceptive will, of necessity, be too low.

- Gather Frequency Scenarios – represent regular gather interval in years (e.g., 2, 4, 6, or 8 years).

- Sex Ratio Scenarios – represent long-term changes to the herd sex structure by favoring removal of horses of one sex over another during the normal selective removal process (e.g., 60% male to 40% female). Note that sex ratios will usually not match among the alternatives. This is because the sex ratio is generated by long-term changes to sex- and age-class specific removal rates and could not be precisely predicted by specifying

population model inputs. In other words, a sex ratio resulting from a given simulation might or might not have been what I was trying to achieve.

- As appropriate, combinations of the above scenarios have been considered. For example, 3-year Contraceptive/Sex ratio-55 would mean the combination of a 3-year contraceptive duration and 55 male:45 female sex ratio. All unspecified parameters are the same as the baseline case, unless otherwise stated.

- Removal-only – One removal-only (no contraceptive application) scenario was included solely for cost comparison.

Step 2. Organize Jenkins Model Input Data and Parameters

Data representative of the Pryor Mountain Herd Management Area (HMA) were compiled and organized in a fashion suitable for the Jenkins wild horse population model (Jenkins 2002). Much of the vital background and operational philosophy for the Jenkins model has already been supplied by Bartholow (2004) and will not be repeated here. Pryor Mountain HMA data and modeling parameters were taken from a Jenkins' model data set and other information supplied by Linda Coates-Markle in early 2004, greatly simplifying this effort. I assumed that the data accurately described the Pryor Mountain population's demographics. A summary of important demographic parameters for this herd is given in Table 3 and a complete listing of the baseline data set for the Pryor Mountain herd is given in Appendix A.

Table 3. Key demographic elements and information concerning compassionate-use fertility control for the Pryor Mountain HMA considered in this analysis.

	Pryor Mountain
Initial population sex ratio (% male)	53
Sex ratio at birth (% male)	51
Age 0-9 female survival (geometric mean %)	89
Age 0-9 male survival (geometric mean %)	87
Average foaling rate age 2-9 (%)	62
Gather trigger (# of horses)	150
Gather efficiency (%)	70
AML (# of horses)	100
AML includes foals?	No
Released mares treated for contraceptive alternatives by age	Foals: 0% 1 & 2 year: 100% 3-13 year: 0% 14+: 100%

Step 3. Exercise the Jenkins Model for Each Scenario

Each scenario was run as a separate simulation using model input parameters to describe the various management actions that might be taken, contraceptive effectiveness, and so on. I have assumed that the Jenkins model provides a reasonably accurate portrayal of population dynamics and that model results can then be used in evaluating a variety of cost-minimization strategies.

Values or settings for the Jenkins' WinEquus model used in Pryor Mountain simulations were:

- Simulations were run for 20 years (producing 21 years of simulation output) with 100 trials each (100 trials is the default)
- Gathering for removal occurred at regular 4-year intervals
- When fertility control was used:
    - Gathers for fertility control occurred regardless of population size
    - Gathers continued after removals to treat additional females to be released (default if the above condition is true). Note, however, that the percentage of females actually treated by age class depends on other model input.
- Scaling factors for annual variation, which interestingly come from Garrott and Taylor (1990) and therefore specifically represent the Pryor Mountain herd:
    - survival probabilities = 1.00 (default)
    - foaling rates = 1.00 (default)
- Correlation between annual variation in survival probabilities and foaling rates = 0.00 (default). According to Linda Coates-Markle (May 2004), there may be some evidence supporting a non-zero correlation for the Pryor Mountain herd due to density-dependent phenomena. However, since these scenarios are explicitly meant to stabilize the population within rather narrow density limits, I left the correlation at zero.
- Initial population size is exact and unsmoothed [different from previous simulations (Bartholow 2004)]
- Foal survival is not density dependent (default)
- Minimum age of sanctuary-bound horses: Not applicable (default)

Step 4. Estimate Dollar Value for Each Management Cost Component

Dollar values were estimated for the main gathering, treating, and selective removal expenditures, along with associated costs related to wild horse management. Dollar figures were taken from Bartholow (2004) and supplemented with information provided by Linda Coates-Markle (Table 4). These costs represent FY 2004 values, but are assumed to increase 3% annually regardless of geographic area to parallel the inflation rate BLM uses for planning. Removal costs include all expenses of gathering and transport to adoption facilities, averaged across all removed horses. Preparation and holding costs include freeze branding and required vaccinations. Adoption costs are largely administrative and include follow-up compliance checks (site visits to adopted horses).

Table 4. Variable cost estimates for the Pryor Mountain wild horse population. Cost estimates were supplied by Linda Coates-Markle, BLM/MT (5/24/2004) and differ from those listed for Montana in Bartholow (2004) because they include labor as a variable cost.

Removal Cost (/horse)	Prep & Holding Cost (/horse/day)	Adoption Cost (/horse)	Compliance Check (/horse)
$800	$40	$1100	$225

Costs used in this analysis for multi-year contraceptives are given in Table 5. Several other potential costs were also considered in the analysis. It was assumed that the minimum gather cost was $15,000, whereas a value of $10,000 was used previously by Bartholow (2004). This comes into play only if the number of animals removed times the appropriate per horse removal cost would be below $15,000. However, for the Baseline and Alternative Baseline scenarios, I used a minimum cost of $3,750 ($15,000/4) to allow gathering and contraceptive application every year in the model, as discussed previously. Though this modification may underestimate costs when real 4-year gathers round up few horses, it represents the best approximation available.

A $5,000 per year HMA census cost was applied for non-gather years to assess contraceptive treatment effectiveness and routine monitoring per the recommendation of Ron Hall (2003). Though the Pryor Mountain herd does not employ census flights due to intensive on-the-ground monitoring, labor costs for this monitoring are roughly equivalent to Hall's cost recommendation and are treated identically in this analysis. However, census costs are problematic for the Baseline and Alternative Baseline scenarios because gathers occur every year in the simulation, though not in reality, and the cost estimation program only tallies a census expense if no horses are gathered. To make up for these "missing" census costs, I added back the $5,000 expense for the 15 years the census would have occurred, averaged over the 20-year period. In other words, I added $3,750 to the average annual cost estimated for the Baseline and Alternative Baseline scenarios to properly account for underestimating census costs (5000*15/20).

Table 5. Estimated per horse costs for contraceptive application. Costs for the 1-year agent represent $20 for the primer and $20 for the booster, plus an additional $66 for labor ($11 per hour times 6 hours per mare, on average) to find and apply the darts. Costs for the 3-year agent are composed of the total cost of a 2-year agent plus additional 12-month time-release pellets. Estimates derived from Linda Coates-Markle (BLM/MT) 9/30/2003 and 5/26/2004.

Contraceptive Duration	Estimated Cost per Horse	Comment
1 year	$106	Remotely applied by darting
2 years	$214	Applied with gather
3 years	$309	Applied with gather

Step 5. Estimate Dollar Costs from Simulated Scenarios

The results of the Jenkins model simulations were summarized and converted to dollar expenses over a 20-year planning horizon. Tallying the total expenditures required all cost estimates previously described, including which ages were eligible for adoption and how long adoptable horses are held. Note that the Pryor Mountain population never contributes unadoptable animals because only young age classes are removed. Results were summarized by software that computed the mean number of horses gathered, removed, and treated by sex and age class for each year of the 20-year simulations, along with average annual costs. In addition, the cost summarization step computed the likely annual variation in costs that would be expected as a result of the variability inherent in the Jenkins model.

Step 6. Conduct Sensitivity Analysis

The Jenkins simulation model captures environmental and demographic variability, but the uncertainty in cost estimates for the various management options remained to be explored. To accomplish this, a sensitivity analysis was performed for the Pryor Mountain population to see where opportunities for cost cutting might lie and which factors contribute most to the bottom line.

Results

Results for the Pryor Mountain HMA are given in Table 6 and Figures 1-4. The results confirm that a four-year gather cycle is a good management decision, though there is not much difference among the alternatives (Figure 1), presumably because the herd is so closely controlled no matter which scenario is chosen – an artifact of this population's low growth rate. Interestingly, a 6-year gather cycle is predicted to be more costly than an 8-year cycle. Annual costs are insensitive to gather efficiency (Figure 2), but are somewhat responsive to slight changes in sex ratio (Figure 3). Even eliminating male removal all together, simulations suggest that the sex ratio would not rise much beyond 53-54% males. In an attempt to further elevate the sex ratio, I increased the female removal rates by 50% (i.e., from 50% on age class 1 to 75%), but this had virtually no affect on the long-term sex ratio and increased the average annual management costs. Results from these experiments are not shown in Table 6.

Average annual cost estimates (Figure 4) are relatively uniform across many of the alternatives, with the exception of the removals-only case. The Alternative Baseline scenario is predicted to be the least expensive, but also has a significant negative effect on the herd's growth rate over the long term. Inspection of the results across the alternatives suggests that growth rates below minus 1.0% are likely too aggressive and cannot be sustained over the 20-year period without significantly increasing the probability of falling below the 100-horse AML. This is also true with scenarios designed to leave more males on the range. Care must be taken to not remove too many mares of prime foaling age lest the population decline below desired population levels.

There is a noteworthy difference reflected in the coefficient of variation between the darting scenarios and the more conventional 2- or 3-year contraceptive scenarios (Table 6). This is

presumably due to the lack of longevity of the 1-year contraceptive used in darting versus the persistent effects of the 2- and 3-year contraceptives.

It is important for the reader to understand that running the same parameters through the Jenkins model repeatedly can produce very different sets of results due to the random nature of the simulations. This randomness can produce variations on the order of 5% or more. Because Table 6 records the mean annual cost from just one set of 100 trials for each scenario, one must use caution when interpreting the results. In short, predicted mean costs for many of the contraceptive scenarios given in Table 6 may or may not be significantly different from one another in a statistical sense. Statistical differences were not assessed in this analysis because one could always increase the number of trials, thus assuring significant differences without any true justification.

Table 6. Summary of results for scenarios of the Pryor Mountain HMA.

Scenario	Average Annual Cost ($)	Percent of Baseline Cost (%)	Median Annual Growth Rate (%)	CV (%)
Baseline	11019[1]	100	-0.7	154.3
Alternative Baseline	7717[1]	70	-4.3	146.7
2-year contraceptive	12877	117	+0.2	82.7
3-year contraceptive	12283	111	0.0	86.3
2-year contraceptive/ Sex ratio-53	10941	99	-0.8	71.0
2-year contraceptive/ Sex ratio-54 (No male removal)	9585	87	-1.3	64.1
3-year contraceptive/ Sex ratio-52	10700	97	-0.2	67.2
3-year contraceptive/ Sex ratio-53 (No male removal)	10157	92	-1.2	62.3
3-year contraceptive/ 2-year gather cycle	12376	112	-1.4	126.0
3-year contraceptive/ 6-year gather cycle	14022	127	-0.1	82.7
3-year contraceptive/ 8-year gather cycle	13206	120	+1.2	59.8
3-year contraceptive / -10% gather efficiency	12294	112	+0.2	77.5
3-year contraceptive / +10% gather efficiency	12141	110	-0.7	91.9
Removals only	16049	146	+0.9	80.0

[1] Includes $3,750 to make up for "missing" non-gather year census costs, but is likely an underestimate due to inability to accurately reflect the $15,000 minimum gather costs when removals are low.

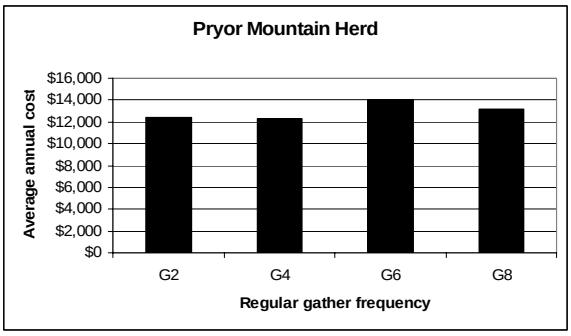

Figure 1. Annualized cost over a 20-year period for four gather frequencies for the Pryor Mountain HMA (G-2, 4, 6, and 8 years, respectively).

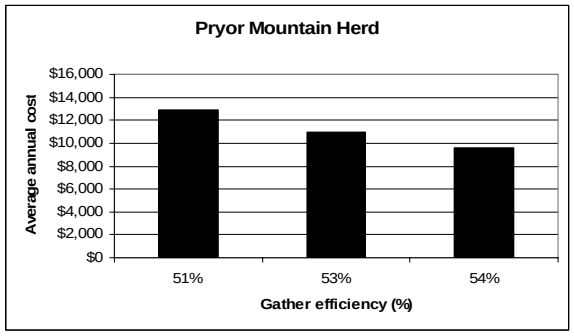

Figure 3. Annualized cost over a 20-year period for three resulting sex ratios associated with 2-year contraceptives for the Pryor Mountain HMA (51, 53, and 54% male, respectively).

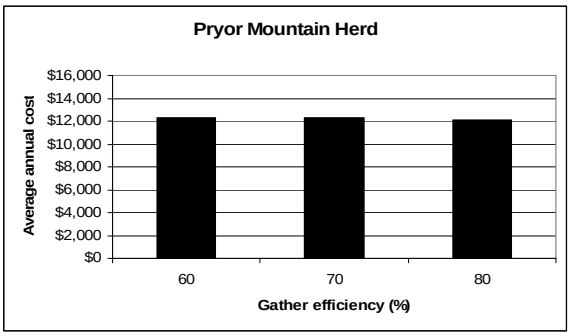

Figure 2. Annualized cost over a 20-year period for three gather efficiencies for the Pryor Mountain HMA (60, 70, and 80%, respectively).

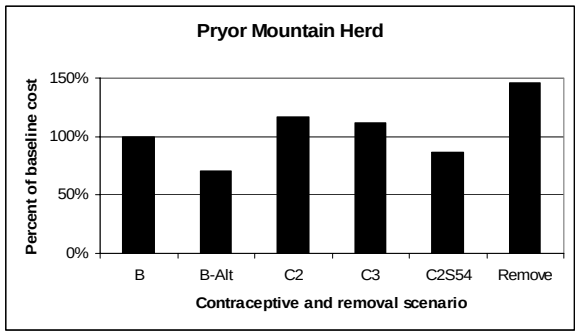

Figure 4. Percent of Baseline cost over a 20-year period for six scenarios.

Sensitivity Analysis for Cost Components and Related Factors

A basic sensitivity analysis was completed for the various elements that contribute to the cost estimate for the Pryor Mountain herd. This analysis tests how sensitive bottom line costs are to small changes in each contributing factor. Figure 5 was generated by changing each cost and management factor ±10% and taking the ratio of the resulting cost fluctuation to the base cost of the Baseline and Alternative Baseline Scenarios for the Pryor Mountain herd. I did not test the sensitivity of varying age thresholds because these are essentially fixed for this herd, though additional scenarios could explore some of these options.

The results indicate that annual monitoring is the cost component that would benefit the bottom line total expenses if it could be reduced regardless of the scenario. Then, for the Baseline Scenario, the next most sensitive cost factors are the costs of adoption, average per day holding costs (the somewhat mislabeled *$/Unadoptable/day* in this case), and number of days held until adoption. Costs related to contraceptive treatment and gathering fall in line next for the Baseline scenario, followed by the minimum gather cost, which contributes little to the sensitivity, indicating that that cost is trivial compared with other management expenses.

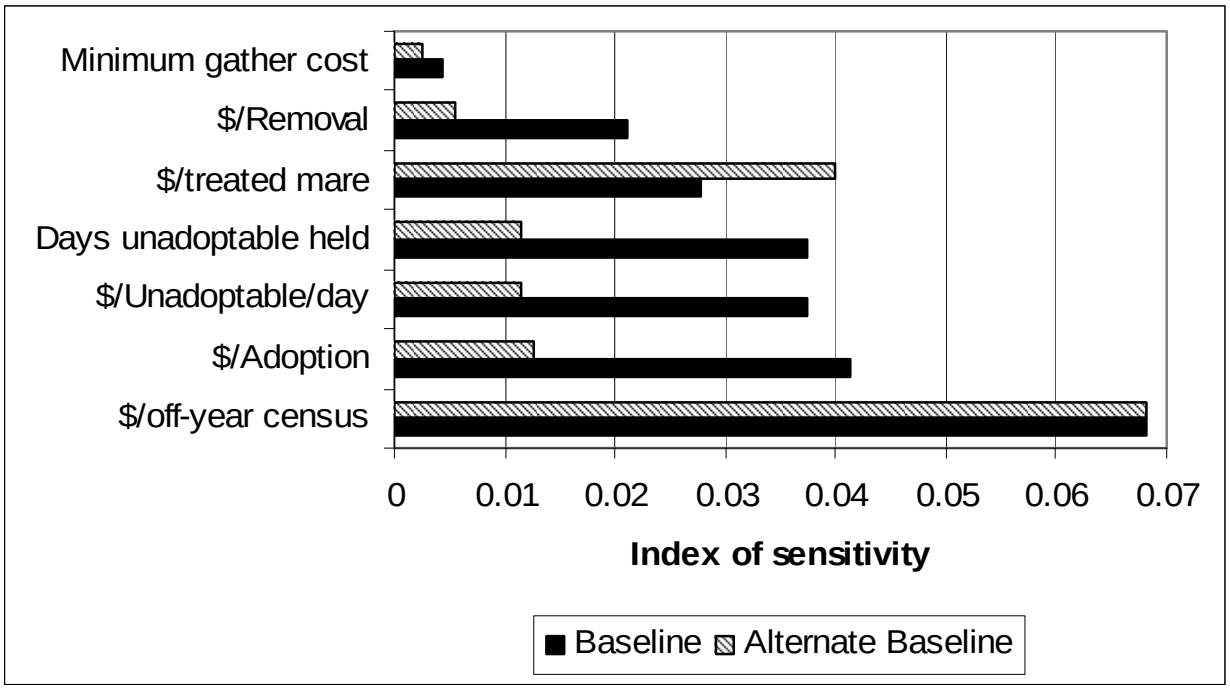

Figure 5. First order sensitivity analysis for management costs and other attributes for the Pryor Mountain herd.

Results for the Alternative Baseline scenario (Figure 5) were considerably different after the monitoring costs. Most factors were far less important for this scenario, relative to those monitoring costs, except for the contraceptive treatment costs. In other words, because this alternative treats far more age classes of adult mares, these additional costs add up significantly. This is not to say that these additional treatment expenses may not be cost-effective, because

they are (Table 6). Rather, it simply says that if these treatment costs could be reduced, the savings would be substantial.

Conclusions and Discussion

The Pryor Mountain herd does not appear to have the same "vitality" as the three populations previously studied (Bartholow 2004). Based on the best, most recently collected data, male and female survival rates for the Pryor Mountain population are estimated to be less than 90% per year, in contrast to above 90% for the other three herds, and moderate foaling rates in the low 60% range are well below the average for the other three populations (72%). Collectively, these differences mean that the intrinsic growth for this herd is far lower than that for other populations, with median annual growth rates near 1% for the Removal-only scenario compared to about 17% for the three populations studied previously. BLM personnel confirm that the current Pryor Mountain growth rate is near zero and has not been above 10% for the last decade (Linda Coates-Markle personal communication). This implies that contraceptive treatment and removals for the Pryor Mountain herd can be far less intensive than for many herds yet still achieve cost savings. It also implies that small changes in management emphasis can result in undesirable negative growth rates.

The Pryor Mountain herd exhibits a higher expected annual variation than any of the herds examined previously. In part, this is a misleading conclusion because the high coefficient of variation can also result if there are no horses ever going into long-term holding facilities, thus creating large differences between gather and non-gather years. However, the Jenkins model simulations also suggest that the population fluctuates more widely *around* the 100-horse AML level rather than generally being *above* that level more often than not, as seen in simulations for other populations. For example, a few of the randomly-generated simulation traces resulted in fewer than 50 horses under the Baseline scenario (Figure 6). This phenomenon points to an additional weakness inherent in how the Jenkins model was applied here that was not discussed by Bartholow (2004): management actions such as contraceptive application would not continue unchanged for 20 years if the result of that application were perceived as jeopardizing the population's persistence. Adaptive assessment and management would prevail.

Caveats discussed in the initial report (Bartholow 2004) apply to this analysis. Several other concerns or imperfections with the Pryor Mountain modeling, particularly with trying to approximate the Baseline scenarios, have also been noted in this report. One additional caveat is worthy of mention. Recall that one goal of compassionate-use fertility control for the Pryor Mountain herd is to help reduce mortality of older mares and help prevent orphaned foals. Simulations conducted here did not include these potential feedback mechanisms and there is no way to conveniently do so. Research must continue to determine whether compassionate-use fertility control is successful in reducing these mortality sources.

Bartholow (2004) made some recommendations for potential modifications to the Jenkins model. Application of the WinEquus model to this specific herd was not a perfect fit for a variety of reasons. If there are other BLM-managed herds similar to the Pryor Mountain population that intermix annual darting and gathering, BLM might consider developing a model that could be

tailored to these sorts of conditions. If this is the only herd, software modifications would not likely be worth the effort.

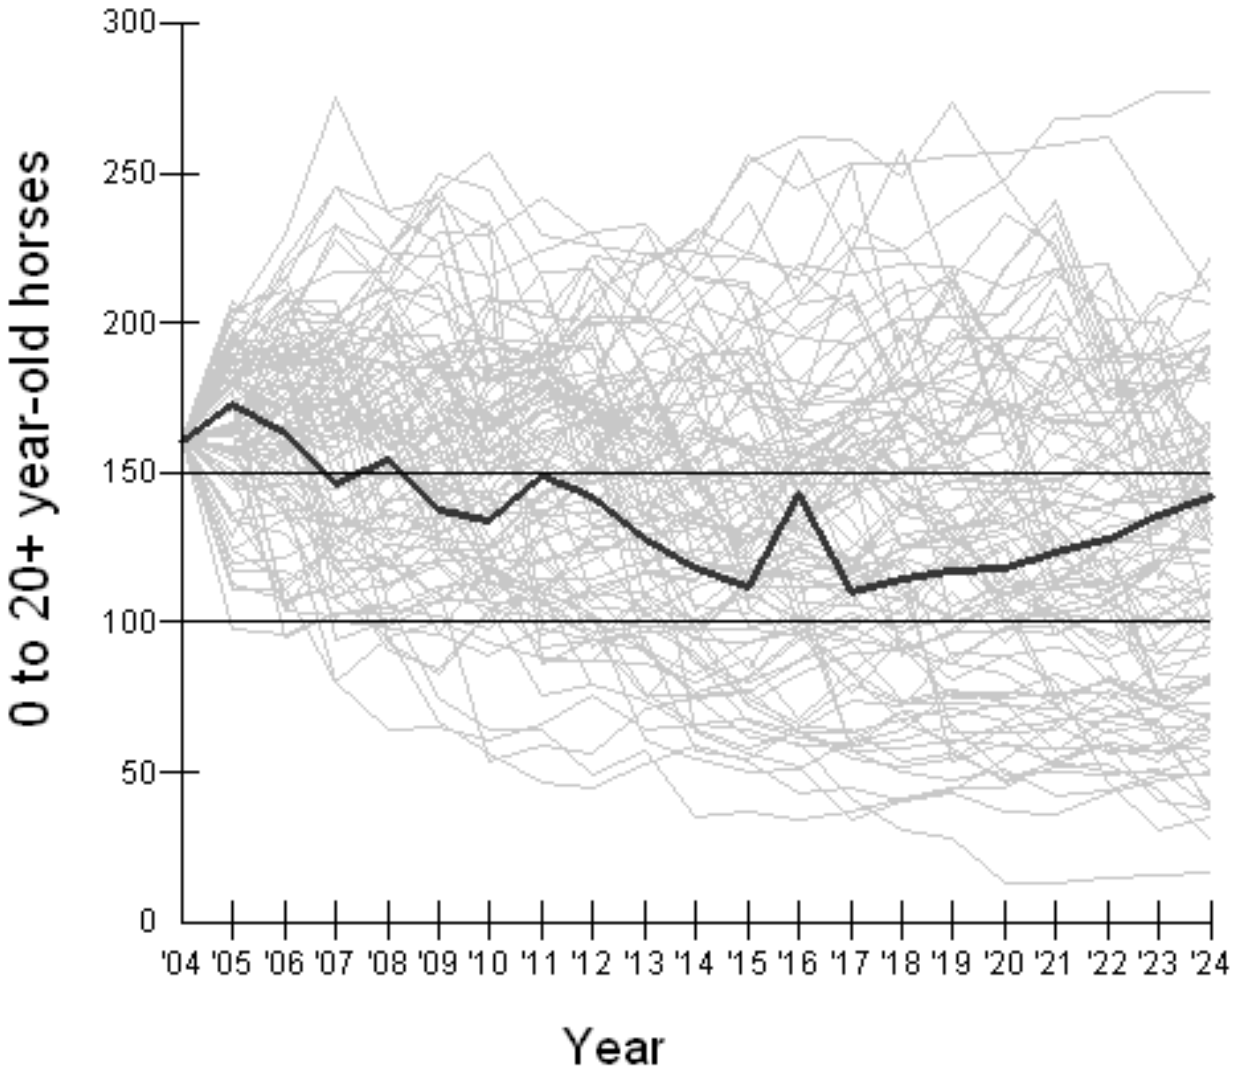

Figure 6. The "Most Typical Trial" simulated by the Jenkins model for the Pryor Mountain Baseline scenario.

Finally, as mentioned in the footnote added to Table 2, since running these simulations, newly collected data are available for the Clan Alpine herd (J.W. Turner, Jr., technical notes on Clan Alpine HMA Wild Horse Survey, June 2004, supplied by Linda Coates-Markle). These notes do not support 4th year effectiveness. Therefore, the cost estimates for scenarios involving the 3-year contraceptive will, of necessity, be too low.

Appendix A. Listings of Jenkins Model Parameters for the Pryor Mountain HMA

The following table provides the basic parameters used in Jenkins' model simulations for the Pryor Mountain herd. Notes imbedded in the files used state that: (1) the initial age structure represented conditions in the fall of 2003 and was considered very accurate; (2) survival estimates represented 1996-2000 conditions, but assumed male survivals were about 97% that of females, as recorded for earlier (1976-1986) data; and (3) foaling rates represented 1996-2003 data, though no mares were ≥ 20 years old. In addition, Linda Coates-Markle confirmed that the initial population numbers by sex and age class should be considered exact counts and not a 90% value as was the case for previous simulations on other herds (Bartholow 2004).

Table A.1. Pryor Mountain Jenkins' model log file for Baseline Scenario. Foaling rates were entered with three digits of precision but only appear with two in this view. Also, log files incorrectly report that gathers do not continue after removals to treat additional females (Steve Jenkins, personal communication). This error has been corrected in this table.

Age Class	Initial Base Population		Survival Probabilities		Foaling Rates	Percentages for Removals		Percentages for Fertility Treatment
	Females	Males	Females	Males		Females	Males	
foal	10	12	0.700	0.700	0.00	0%	0%	0%
1	4	8	0.800	0.800	0.07	9%	9%	100%
2	8	8	0.931	0.902	0.48	9%	9%	100%
3	6	1	0.931	0.902	0.47	9%	9%	0%
4	4	7	0.930	0.901	0.64	4%	4%	0%
5	7	3	0.929	0.901	0.63	0%	0%	0%
6	6	6	0.929	0.900	0.64	0%	0%	0%
7	5	8	0.927	0.899	0.62	0%	0%	0%
8	4	3	0.925	0.897	0.71	0%	0%	0%
9	3	2	0.923	0.895	0.79	0%	0%	0%
10-14	16	17	0.907	0.879	0.58	0%	0%	50%
15-19	3	8	0.816	0.791	0.08	0%	0%	100%
20+	0	2	0.207	0.207	0.00	0%	0%	100%

Sex ratio at birth: 51% males
Scaling factors for annual variation: survival probabilities = 1.00, foaling rates = 1.00
Correlation between annual variation in survival probabilities and foaling rates = 0.00

Management by removals and fertility control
Starting year is 2004
Gathering occurs at regular interval of 1 years
Initial gather year is 2004
Gathers for fertility treatment occur regardless of population size.
Gathers continue after removals to treat additional females.
Threshold population size for gathers is 150.
Target population size following removals is 100.
Foals are excluded from AML.
Percent of population that can be gathered = 70%.
Percent effectiveness of fertility control: year 1 is 90%, year 2 is 0%, year 3 is 0%, year 4 is 0%, year 5 is 0%.

Table A.2. Pryor Mountain Jenkins' model log file for the more conventional 2-year contraceptive scenarios.

Age Class	Initial Base Population		Survival Probabilities		Foaling Rates	Percentages for Removals		Percentages for Fertility Treatment
	Females	Males	Females	Males		Females	Males	
foal	10	12	0.700	0.700	0.00	0%	0%	0%
1	4	8	0.800	0.800	0.07	50%	50%	100%
2	8	8	0.931	0.902	0.48	50%	50%	100%
3	6	1	0.931	0.902	0.47	50%	50%	0%
4	4	7	0.930	0.901	0.64	25%	25%	0%
5	7	3	0.929	0.901	0.63	0%	0%	0%

Appendix B. Program to Estimate Economic Costs from WinEquus Simulation Results

As mentioned in Appendix A, the Jenkins model was used to simulate the population's alternative futures and the simulation results were written to a text file. A Microsoft VisualBasic program was constructed to read these results and calculate average yearly costs as well as overall average costs for a 20-year period. User-specified input to this program (Figure B.1) includes estimates for the individual components of the variable costs for each state.

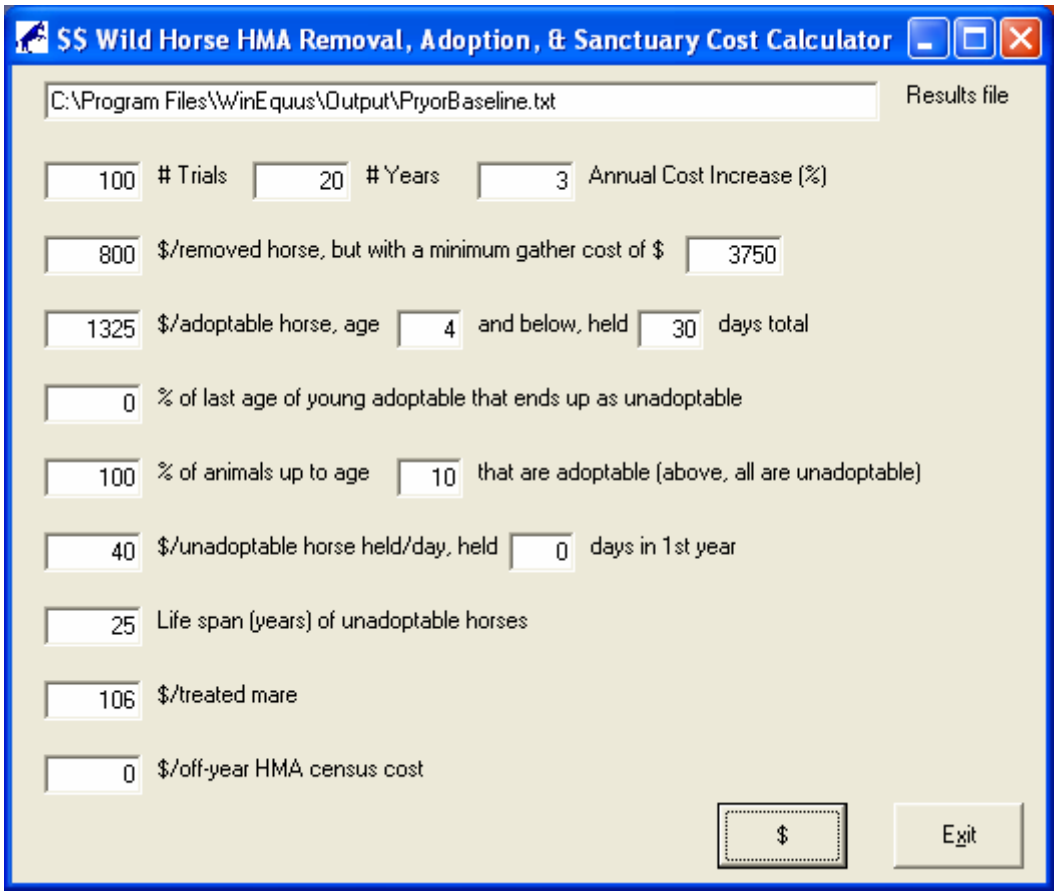

Figure B.1. Input parameters for companion program to estimate costs of each specific simulation run with the Jenkins modeling software. The image pictured is for the Baseline case and is considerably different from the more conventional scenarios. Note that since the Pryor Mountain herd produces only adoptable horses, cost values for that category will never apply. However, adoptable horses still accrue daily holding costs.

The number of *trials* and number of *years* are set to match parameters in the Jenkins model set-up. The number of trials and number of years capture both the variability inherent in the stochastic simulation model and any population adjustments in age and sex structure that occur over about one horse life span. The *annual cost increase* adjusts all future expenditures for the rate of inflation. The *$/removed horse* reflects the cost of gathering and removal averaged across all removed horses. *Minimum gather cost* is just what it says: i.e., even if the number of gathered horses is small, there would be a minimum cost just to have a gather. The *$/adoptable horse* reflects the combined cost of adoption and compliance checks (Table 3). All horses up to the

first age listed are assumed to be adoptable, except for the *% of last age of young adoptable that ends up as unadoptable*. In other words, a certain percentage of the oldest age class of adoptable animals is considered unadoptable. [Note that since the Pryor Mountain herd does not produce unadoptable horses, this value is set to zero and therefore cost values for "unadoptable" horses will never apply.] Adoptable animals are held for the first number of *days* listed prior to adoption. A *% of animals up to age* xx are also considered adoptable. Unadoptable animals accrue a cost of *$/unadoptable horse held/day*, are held *days in 1st year*, and 365 days thereafter through their *life span*. Note that adoptable horses also accrue the same holding cost for the days they are held prior to adoption. Contraceptive application is reflected in the *$/treated mare* cost estimate. *$/off-year HMA census cost* reflects any additional costs involved with a contraceptive program in non-gather years (typically years 2 through 4), such as flight costs to assess treatment effectiveness and perform other routine monitoring (Hall 2003). This last item would be zero except for scenarios involving contraceptive treatment.

The program reads the simulation results, averaging the costs for each year over the number of trials for which the software was run, and then summarizes the results across all simulation years. The output from this program looks like that shown in Table B.1.

The economic model output contains the name of the Jenkins model simulation results file and echoes the input values used. *Expenses* are inflation-adjusted values and *CV* is the coefficient of variation: i.e., the percent that expenses might be expected to vary annually given the variability reflected in the stochastic population model. The CV value is calculated as one standard deviation from the mean value for the year divided by that mean value. The remaining values listed (population size, sex ratio, number gathered, number treated, number removed, number adopted, number unadoptable, number held, and number dying) also represent annual averages, rounded to the nearest animal. The *mean* values listed near the bottom are averages across the number of years, except for those associated solely with gathering (population size, sex ratio, number gathered, number treated, number removed, number adopted, number unadoptable), which are averaged across the number of gathers. Finally, the program provides the percentage of the mean annual expense attributable to the total cost of adoptions, long-term holding, and contraceptive treatment.

Scanning the values listed in Table B.1, one can usually see how the population is adjusting through time to the management strategy implemented in the population modeling software. It is also a useful way to assess whether the selective removal rates specified in the Jenkins model have been effective in reaching the specified herd-specific AML – if foals are included in the AML.

Table B.1. Example output from cost estimator program for Pryor Mountain Baseline Scenario.

Abstract

Abstract

In female rats, ovariectomy (OVX) is associated with increased body fat and insulin resistance, and estradiol replacement prevents these alterations. These metabolic changes related to the estrogen-deficient state might be due, in part, to alterations in skeletal muscle substrate metabolism. We tested the hypothesis that estradiol affects the regulation of enzymes involved in substrate oxidation and storage within skeletal muscle. Specifically, we examined enzymes involved in the regulation of glycogen synthesis (glycogen synthase [GS]), glycolysis (phosphofructokinase [PFK]), tricarboxylic acid cycle activity (citrate synthase [CS]), and [beta]-oxidation ([beta]-hydroxyacyl-CoA dehydrogenase [[beta]-HADH]). Twenty-two, female Sprague-Dawley rats (7 to 8 weeks old) were separated into 3 groups: OVX + placebo (P; n = 8), OVX + estradiol (E_2; n = 8), and sham-operated (S; n = 6). Rats from E_2 and P groups were pair-fed to the S group to control for OVX-induced changes in food intake. After 16 days, activities of GS, PFK, CS, and [beta]-HADH were measured in vastus medialis muscle. GS fractional velocity was significantly lower (*P* [lt] .05) in P (mean [plusmn] SE; 39.7% [plusmn] 6.2%) compared with both S (61.9% [plusmn] 8.8%) and E_2 (65.8% [plusmn] 8.4%) rats. In addition, E_2 rats (41.4 [plusmn] 2.0) had significantly higher (*P* [lt] .05) CS activity than P (34.9 [plusmn] 2.0) and S (33.9 [plusmn] 1.4 [mu]mol/min/g) groups. There was no effect of OVX or estradiol replacement on [beta]-HADH or PFK. Our results suggest that, independent of alterations in food intake, estradiol availability affects the regulation of enzymes involved in nonoxidative glucose disposal (GS) and oxidative metabolism (CS) in skeletal muscle.

Impact of ovariohysterectomy and food intake on body composition, physical activity, and adipose gene expression in cats[1]

K. R. Belsito,* B. M. Vester,* T. Keel,† T. K. Graves,†‡ and K. S. Swanson*†‡[2]

*Department of Animal Sciences, †Department of Veterinary Clinical Medicine, and ‡Division of Nutritional Sciences, University of Illinois, Urbana 61801

ABSTRACT: The mechanisms contributing to BW gain following ovariohysterectomy in domestic cats are poorly understood. Moreover, the effects of food restriction to maintain BW following spaying have been poorly studied. Thus, our primary objective was to determine the effects of spaying and food restriction to maintain BW on adipose and skeletal muscle mRNA abundance and activity levels in cats. After a 4-wk baseline period (wk 0), 8 adult (approximately 1.5 yr old) domestic shorthair cats were spayed and fed to maintain BW for 12 wk. After 12 wk, cats were fed ad libitum for an additional 12 wk. Body composition was determined, activity levels were measured, and adipose and muscle biopsies were collected at wk 0, 12, and 24. Fasting blood samples were collected at wk 0, 6, 12, 18, and 24. To maintain BW post-spay, food intake was decreased ($P < 0.05$) by 30%. During this phase, mRNA abundance of adipose tissue lipoprotein lipase and leptin was decreased ($P < 0.05$), representing only 52 and 23% of baseline expression, respectively. Interleukin-6 mRNA, however, was increased ($P < 0.05$) 2-fold. Physical activity was decreased ($P < 0.05$) by wk 12, most dramatically during the dark period (approximately 20% of baseline activity). During ad libitum feeding (wk 12 to 24), food intake, BW, body fat percentage, and total fat mass were greatly increased ($P < 0.05$). Compared with wk 0, circulating leptin concentrations tended to increase ($P < 0.10$) by wk 18 and 24 (4.45 vs. 10.02 and 9.14 ng/mL, respectively), whereas glucose (91 vs. 162 mg/dL) and triacylglyceride (30 vs. 48 mg/dL) concentrations were increased ($P < 0.05$) by wk 24. Adipose tissue lipoprotein lipase, hormone sensitive lipase, and adiponectin mRNA were decreased ($P < 0.05$) at wk 24. Adipose interleukin-6 mRNA was increased ($P < 0.05$) at 24 wk. Physical activity was further decreased ($P < 0.05$) by wk 24, during the light (60% of baseline) and dark (33% of baseline) periods. In summary, spaying and food restriction affect physical activity levels and several genes associated with lipid metabolism (decreased lipoprotein lipase), food intake (decreased leptin expression), and insulin insensitivity (increased interleukin-6). By identifying these changes, targets for nutritional intervention or lifestyle management have been identified that may curb the risk of obesity and related disorders in spayed cats.

INTRODUCTION

Feline obesity has rapidly increased over the past few decades, with 30 to 40% of cats in the United States being considered overweight or obese (Scarlett et al., 1994; Lund et al., 2005). Although gonadectomy is an effective strategy for controlling overpopulation, it is a risk factor for feline obesity. The effects of estrogen on metabolic rate and disease risk are evident but poorly understood. Estrogen not only has receptors in the hypothalamus, but has also been shown to interact with leptin and increase its action, suggesting a role in appetite regulation (Cooke and Naaz, 2004). Estrogen has also been associated with increased voluntary exercise, with ambulatory activity decreasing in ovariectomized rats (Shimomura et al., 1990). Although these interactions have been demonstrated, the mechanisms contributing to increased food intake and BW gain in spayed cats are unknown.

Because altered glucose and lipid metabolism accompany BW gain, identifying differences in skeletal muscle and adipose tissue after spaying is of interest. Skeletal muscle plays an important role in glucose metabolism and accounts for approximately 80% of insulin-mediated glucose uptake (Defronzo et al., 1981), a response that is diminished in obese individuals. In addition to

its role in energy storage, adipose tissue is now accepted as an active endocrine organ intricately involved in energy homeostasis and metabolism. The metabolic dysfunction that occurs in muscle after spaying, with BW gain, or both, is not entirely understood, but may be partly attributed to low-grade inflammation. It is now well accepted that much of this inflammation is derived from inflammatory mediators produced by immune cells present in adipose tissue. Because estrogen receptors are expressed in several cell types in adipose tissue including preadipocytes and macrophages (Gulshan et al., 1990; Venkov et al., 1996), studying the effects of spaying on adipose tissue function is justified.

Recent feline genome sequencing initiatives have allowed the measurement of gene transcripts that may aid in our understanding of spaying and its effect on adipose and muscle metabolism. The objectives of this experiment were 2-fold. Because the effects of food restriction to maintain BW following spaying have been poorly studied, we first aimed to evaluate the effects of spaying and 12 wk of food restriction on BW, body composition, activity levels, blood metabolites, and mRNA abundance of genes associated with lipid metabolism and inflammation in subcutaneous adipose and skeletal muscle tissues of adult cats. Second, we aimed to measure these same outcomes in cats fed ad libitum for an additional 12 wk.

MATERIALS AND METHODS

All procedures were approved by the University of Illinois Institutional Animal Care and Use Committee before experimentation.

Animals and Diet

Eight adult (mean age = 1.6 ± 0.13 yr old; mean BW = 3.52 ± 0.72 kg) female domestic shorthair cats (Liberty Research Inc., Waverly, NY) were used. Cats were individually housed in stainless steel cages measuring 0.61 × 0.61 × 0.61 m in the animal facility of the Edward R. Madigan Laboratory at the University of Illinois. Room dimensions were 7.32 m wide × 9 m long × 3.96 m high. The room was climate-controlled (22°C) with a 16 h light:8 h dark cycle. Cats were fed a commercially available, nutritionally complete dry cat food (Iams Original Formula Cat Food, Procter and Gamble, Dayton, OH) throughout the experiment and were given ad libitum access to water. The primary ingredients in the diet included chicken, chicken by-product meal, corn grits, corn meal, chicken fat, fish meal, and dried beet pulp. Analyzed dietary chemical composition is listed in Table 1.

Table 1. Analyzed chemical composition of diet fed to spayed cats

Item	%, as fed

OM, % of DM	93.19
Acid hydrolyzed fat, % of DM	22.35
CP, % of DM	36.13
Total dietary fiber, % of DM	5.71
GE, kJ/g	22.97

Experimental Design

Experimental design is presented in Figure 1. Four weeks before the experiment, cats were acclimated to the diet and fed at a level to maintain BW. During this time, cats were also acclimated to a daily activity schedule that allowed for group interaction but individual housing and feeding. This period also allowed for an accurate estimate of the caloric intake required to maintain a stable BW before treatment. Cats were housed in pens individually for 7 h/d (0800 to 0900 h; 1000 to 1200 h; 1500 to 1900 h) and group housed for 17 h/d in the room, including the dark period. After the baseline period (wk 0), all activity and body composition measurements were performed and blood and tissue samples were collected. Cats were then spayed and studied for 24 additional wk. At wk 0 (pre-spay), 6, 12, 18, and 24, fasted blood samples were collected for glucose, leptin, ghrelin, triacylglyceride (**TG**), NEFA, fructosamine, and insulin analysis. Subcutaneous abdominal adipose and LM biopsies also were collected at wk 0, 12, and 24.

Daily food intake and twice weekly BW were measured throughout the study. In the 12 wk after spaying, food intake was adjusted so that BW was maintained within 200 g of baseline BW. After wk 12 measurements, cats were fed ad libitum for an additional 12 wk. Periods of 12 wk were chosen based on previous experiments demonstrating that caloric intake reaches a stable plateau by approximately wk 12 after spaying (Flynn et al., 1996).

Body Composition

Lean mass, fat mass, and bone mineral mass were determined using dual-energy x-ray absorptiometry, which has been previously validated in cats (Speakman et al., 2001). Determinations were conducted after ovariohysterectomy and tissue biopsy, while still under sedation. Cats were placed in ventral recumbency and body composition was analyzed using a Hologic model QDR-4500 Fan Beam x-ray Bone Densitometer and software (Hologic Inc., Waltham, MA).

Activity Level Assessment

Voluntary activity levels was evaluated using Actical activity collars (Mini Mitter, Bend, OR), which were worn around the neck for 9 consecutive days before wk 0, 12, and 24. The collars contained omnidirectional sensors capable of accurately incorporating both intensity and duration of movements. Once the collars were

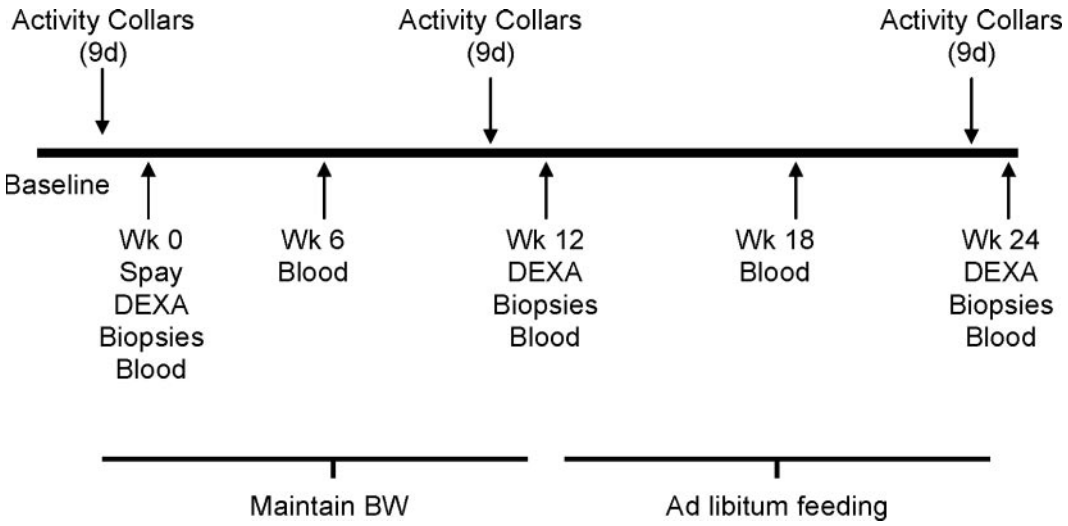

Figure 1. Timeline and data collection time points of experiment. DEXA = dual-energy x-ray absorptiometry.

removed, the Actical software analyzed the data compiled by the collar and converted it into arbitrary numbers referred to as activity counts. In the current data set, average activity was presented in activity counts per epoch (epoch length = 0.25 min). Actical software allowed for the determination of average activity counts per epoch during the light and dark periods without human interference.

Ovariohysterectomy

Food was withheld for at least 8 h before ovariohysterectomy. Cats were given free access to water. Cats were premedicated with ketamine and equal parts valium (11 mg/kg intramuscular), and anesthesia was induced and maintained with isoflurane in 100% oxygen. Briefly, a ventral medial incision was made and ovariohysterectomy was performed by T. K. Graves and T. Keel using standard techniques. Postsurgery, butorphanol (0.22 mg/kg) was administered to alleviate discomfort. All cats were completely recovered within 2 wk postsurgery, returning to their normal food intake and activity levels.

Sample Collection and Analysis

Representative diet samples were collected and ground using a Wiley mill (model 4, Thomas Scientific, Swedesboro, NJ) through a 2-mm screen and dry ice in preparation for chemical analyses. Diet samples were analyzed for DM and OM according to AOAC (1984). Crude protein was determined according to AOAC (1995) using a Leco Nitrogen/Protein Determinator (model FP-2000, Leco Corporation, St. Joseph, MI). Fat concentrations were measured by acid hydrolysis (AACC, 1983) followed by ether extraction (Budde, 1952). Gross energy was measured by use of a bomb calorimeter (Model 1261, Parr Instrument Co., Moline, IL). Total dietary fiber concentration was determined according to Prosky et al. (1992).

Fasting (8 h) blood samples (3 and 8 mL) were collected at wk 0, 6, 12, 18, and 24 via jugular venipuncture. One sample (3 mL) was collected into BD Vacutainer tubes (#367835, 5.4 mg of K_2 EDTA, Becton, Dickinson, and Company, Franklin Lakes, NJ) for plasma. The second sample (8 mL) was first used for glucose measurement (1 drop needed) using the glucose oxidase method by utilizing a Precision G Blood Glucose Testing System (Medisense, Bedford, MA). The remainder of the second blood sample was transferred to the appropriate serum separator tubes (#367985, Becton, Dickinson, and Company). All tubes were centrifuged (13,000 $\times$ g for 15 min at 4°C) within 1 h of collection. Following centrifugation, supernatant was collected, separated into respective cryovials, and stored at −80°C until further analysis.

Serum fructosamine, TG, and NEFA were analyzed by the University of Illinois Clinical Diagnostic Laboratory (Urbana). Plasma leptin concentrations were determined using a commercially available RIA kit (Multispecies Leptin RIA Kit, Linco Research, St. Louis, MO) previously validated in cats (Backus et al., 2000). Serum insulin concentrations were determined using a commercial RIA kit (Double Antibody RIA, Diagnostic Systems Laboratories Inc., Webster, TX) validated in the cat by the manufacturer. Serum total ghrelin concentrations were determined using a commercially available enzyme immunoassay kit (Ghrelin Rat EIA Kit, Phoenix Pharmaceuticals Inc., Belmont, CA) following a 10-fold dilution of serum. Insulin, leptin, and ghrelin data were analyzed using GraphPad Software (Prism Software, San Diego, CA) before statistical analyses were performed.

At wk 0, 12, and 24, approximately 1 g of subcutaneous abdominal adipose tissue and 1 g of LM was collected following an overnight fast. Cats were sedated using atipamazole (0.02 mg/kg), atropine (0.04 mg/kg), and medetomadine (0.02 mg/kg). Samples were immediately flash frozen in liquid nitrogen and stored at −80°C until further analyses.

Total RNA Extraction and Quantitative Reverse Transcriptase-PCR

Total cellular RNA was isolated from adipose tissue and skeletal muscle using Trizol (Invitrogen, Carlsbad, CA). The concentration and purity of RNA was determined using an ND-1000 spectrophotometer (Nanodrop Technologies, Wilmington, DE). Conversion of RNA to complementary (**c**)DNA was carried out using methods described by the ABI cDNA Archive kit (Applied Biosystems, Foster City, CA). Isolated cDNA was amplified using quantitative reverse transcriptase-PCR on an ABI Prism 7900HT Sequence Detection System (Applied Biosystems). Gene-specific primers for adiponectin, IL-6, IL-1, uncoupling protein 2, lipoprotein lipase (**LPL**), vascular endothelial growth factor, chemokine receptor 5, estrogen receptor 1, hormone-sensitive lipase (**HSL**), leptin, toll-like receptor 4, tumor necrosis factor α (**TNF-α**), and glyceraldehyde-3-phosphate dehydrogenase, were designed using Primer Express 2.0 Software (Perkin Elmer, Boston, MA; Table 2). The mRNA abundance for all of the genes was tested in adipose tissue, whereas only estrogen receptor 1, uncoupling protein 2, LPL, and HSL were measured in skeletal muscle.

The PCR mixture contained 1 ng/μL and 10 ng/μL of cDNA from adipose and skeletal muscle tissue, respectively, 15 pmol of each primer, and 5 μL of SYBR Green (Applied Biosystems). The final volume was adjusted to 10 μL using sterile deionized water. The 18S ribosomal RNA gene was used as an internal standard. Originally, glyceraldehyde-3-phosphate dehydrogenase was attempted as an internal standard. However, expression levels were affected over time and were determined to be inappropriate for our data set. Data analyses were carried out with sequence detection system software (Applied BioSystems).

Statistical Analyses

The experimental design consisted of a single factor (week) experiment with repeated measures. Data were analyzed using the MIXED procedure (SAS Inst. Inc., Cary, NC). Cat and week were tested as fixed effects. Least squares means for food intake and BW data were compared with wk 0, and least squares means for all other data were compared between week by using the least significant difference method when the main effects were significant. Results are presented as means ± SEM. The correlation between leptin and body fat mass was analyzed using the Pearson correlation in SAS. Relative calculated levels of mRNA in fat and skeletal muscle tissues were analyzed using MIXED procedure of SAS. Again, cat and week were tested as fixed effects. A probability of $P < 0.05$ was considered significant and $P < 0.10$ was considered to be a trend.

RESULTS

Food Intake and BW

To maintain ideal BW during the first 12 wk after spaying, food intake was decreased, with decreases ($P < 0.05$) occurring by wk 7 (30.6% by wk 12; Figure 2). After 12 wk, cats were fed ad libitum. As expected, a large increase in food intake resulted from wk 12 to 13, followed by a gradual decline that was still greater ($P < 0.05$) at wk 23 than at baseline (40.5% increase from wk 12 to 24). Food intake at wk 24 was not different from baseline.

Body Composition

Total fat mass and bone mineral content were greater ($P < 0.05$) at wk 24 compared with wk 0 and 12 (Table 3). Lean mass also was greater at wk 24 compared with wk 0 and tended ($P < 0.10$) to be greater than at wk 12. Body fat percentage did not differ from wk 0 to 12, but was greater ($P < 0.001$) at wk 24 compared with wk 0 and 12. Although lean mass (g) increased from wk 0 to 24, the dramatic change in fat mass resulted in decreased ($P < 0.05$) lean mass percentage at wk 24 compared with wk 0 and 12. Bone mineral content percentage increased ($P < 0.05$) from wk 0 to 24, which

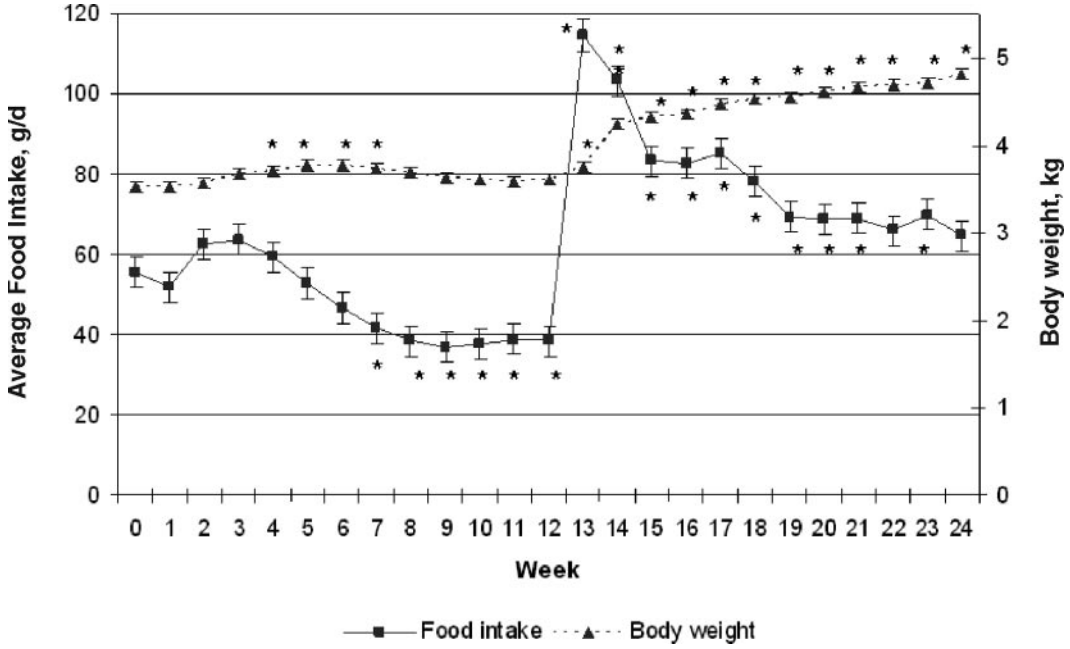

Figure 2. Average food intake and BW of spayed cats. Cats were food restricted following ovariohysterectomy (wk 0) to maintain baseline BW for 12 wk and then fed ad libitum for another 12 wk. *Means that differ from wk 0 ($P < 0.05$), n = 8. Food intake SEM = 3.80; BW SEM = 0.06.

was likely the result of an increased need for skeletal support of a greater BW.

Physical Activity and Intensity

From wk 0 to 24, total daily activity decreased by 52%, decreasing ($P < 0.001$) from 30.0 to 14.3 ± 1.82 mean activity counts per epoch. In the first 12 wk, activity during light hours did not change, but activity during the dark period decreased ($P < 0.001$) dramatically (Figure 3). From wk 12 to 24, total activity decreased ($P < 0.05$) further, primarily because of the decreased ($P < 0.05$) activity during light hours.

Blood Metabolites

By wk 24, cats had increased ($P < 0.001$) serum glucose and TG concentrations compared with wk 0, 6, 12, and 18 (Table 4). Circulating leptin also tended to be greater ($P < 0.10$) at wk 18 and 24 compared with wk 0.

Adipose and Skeletal Muscle Tissue mRNA Abundance

Adipose LPL mRNA abundance was decreased ($P < 0.05$) at wk 12 and 24 compared with wk 0 (Table 5). Similarly, HSL mRNA abundance was decreased ($P < 0.05$) at wk 24 compared with wk 0 and 12. In this study, TNF-α mRNA tended to decrease ($P < 0.10$) by wk 12 compared with wk 0, but was not different at wk 24 (Table 5). Adipose IL-6 mRNA expression was increased ($P < 0.05$) at wk 12 and 24 compared with wk 0 (Table 5). Adipose leptin mRNA expression levels decreased ($P < 0.05$) at wk 12, but were not different at wk 24 compared with wk 0 (Table 5). Adipose adiponectin mRNA was not different between wk 0 and 12, but was decreased ($P < 0.05$) at wk 24 (Table 5). Skeletal muscle mRNA abundance was not changed ($P > 0.05$) throughout the experiment (data not shown).

DISCUSSION

Soon after spaying, most cats have a significant increase in food intake, leading to BW gain that is pri-

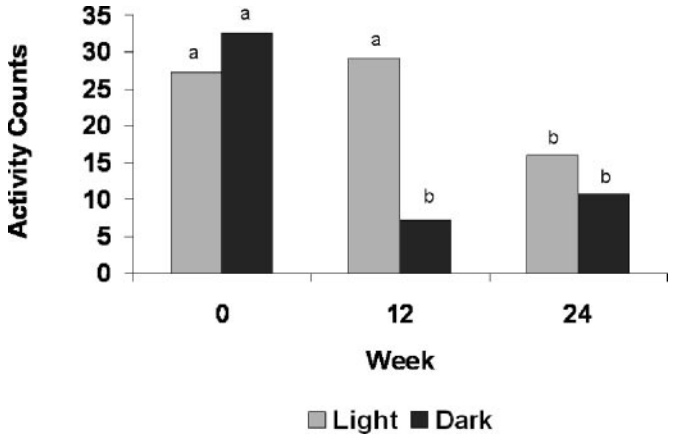

Figure 3. Average activity levels of spayed cats during dark and light periods. Data compiled by activity collars were converted into arbitrary numbers referred to as activity counts by Actical software (Mini Mitter, Bend, OR). Average activity is presented in activity counts per epoch (epoch length = 0.25 min). [a,b]Within an activity period [when lights were on (light) vs. when lights were off (dark)], means lacking a common letter differ ($P < 0.05$); n = 8; light SEM = 2.18; dark SEM = 2.10.

Table 3. Body composition of cats during wk 0, 12, and 24 of the study[1]

Item	Wk 0	Wk 12	Wk 24	SEM
Total fat, g	750.78[a]	706.99[a]	1,644.96[b]	90.17
Total lean, g	2,742.26[a]	2,862.97[ab]	3,086.67[b]	40.72
Total BMC, g	40.72[a]	43.79[a]	64.60[b]	2.51
Fat, %	20.55[a]	18.58[a]	33.50[b]	0.99
Lean, %	78.29[a]	80.18[a]	65.15[b]	0.98
BMC, %	1.16[a]	1.24[ab]	1.35[b]	0.05

[a,b]Least squares means within a row lacking a common superscript differ ($P < 0.05$), n = 8.

[1]Body composition was measured following a baseline period (wk 0), 12 wk after spay and food restriction to maintain BW (wk 12), and another 12 wk of ad libitum feeding and consequent BW gain (wk 24). BMC = bone mineral content.

marily in the form of fat mass. Obesity-related insulin resistance and alteration in blood lipids soon follow, increasing the risk of diabetes mellitus and other disorders. Although these physiologic responses are commonly reported, few studies have been designed to identify contributing mechanisms. Moreover, the effects of food restriction to maintain BW following spaying have been poorly studied to date. Therefore, our primary objective was to evaluate the effects of spaying and 12 wk of food restriction on activity levels and mRNA abundance of genes associated with lipid metabolism and inflammation in subcutaneous adipose and skeletal muscle tissues of adult cats. Our secondary objective was to measure these responses when cats were fed ad libitum for an additional 12 wk.

Similar to what has been reported by other research groups, our data suggest that caloric restriction of approximately 30% is required to avoid BW gain following ovariohysterectomy in cats. Flynn et al. (1996) and Hoenig et al. (2002) reported a reduced caloric intake of 37 and 13%, respectively, to maintain baseline BW in spayed cats. Because cats were fed to maintain BW for the first 12 wk, body composition and blood metabolite concentrations were not altered during this period. This allowed for the measurement of activity and gene expression changes due to spaying and food restriction without the bias of BW gain.

Effects of Spaying and Food Restriction on Physical Activity

Reduced physical activity has been suggested as a contributing factor to increased BW gain following ovariohysterectomy but has not been quantitatively measured in cats. Flynn et al. (1996) subjectively measured activity in cats following ovariohysterectomy, reporting no significant differences from pre-spay. However, in that study, cats were only observed for 5 to 10 min/d over the course of a few weeks. The use of activity collars in this experiment allowed for continuous monitoring over several days during dark and light periods and without human interference. Our results demonstrated a dramatic decrease in physical activity after gonadectomy and food restriction, especially during the dark period. To our knowledge, these data are the first of its kind to be reported in spayed cats. Given this interesting outcome, further research is needed to distinguish cause-and-effect relationships between physical activity and the physiological and gene expression changes observed in this experiment.

Effects of Spaying and Food Restriction on Adipose mRNA Abundance

Lipid metabolism is commonly altered following ovariohysterectomy, BW gain, or both (Hoenig et al.,

Table 4. Fasting blood glucose, insulin, triacylglyceride (TG), NEFA, leptin, and ghrelin concentrations in spayed cats[1]

Item	Wk 0	Wk 6	Wk 12	Wk 18	Wk 24	SEM
Glucose, mg/dL	90.88[a]	106.50[a]	77.00[a]	109.75[a]	162.00[b]	10.88
Insulin, μIU/mL	3.86	3.72	6.26	4.12	3.32	0.50
TG, mg/dL	30.25[a]	35.38[a]	24.50[a]	33.50[a]	48.13[b]	3.91
NEFA, mEq/L	0.49	1.58	0.54	0.53	0.59	0.24
Leptin, ng/mL	4.45[y]	4.12[xy]	3.65[x]	10.02[z]	9.14[z]	1.32
Ghrelin, ng/mL	2.38	3.97	3.73	3.90	3.54	1.24

[a,b]Least squares means within a row lacking a common superscript differ ($P < 0.05$); n = 8, except wk 6 NEFA (n = 5) and wk 18 leptin (n = 7).

[x–z]Least squares means within a row lacking a common superscript differ ($P < 0.10$).

[1]Blood samples were collected following a baseline period (wk 0), 6 and 12 wk after spay and food restriction to maintain BW (wk 6 and 12), and another 6 and 12 wk of ad libitum feeding and consequent BW gain (wk 18 and 24).

Table 5. Relative mRNA expression in adipose tissue in spayed cats[1]

mRNA	Wk 0	Wk 12	Wk 24
Lipoprotein lipase	$968^{a} \pm 159$	$504^{b} \pm 110$	$543^{b} \pm 50$
Hormone sensitive lipase	$702^{a} \pm 120$	$513^{ab} \pm 98$	$436^{b} \pm 49$
Tumor necrosis factor	$4{,}911^{x} \pm 957$	$2{,}110^{y} \pm 620$	$3{,}779^{x} \pm 1409$
IL-6	$210^{a} \pm 18$	$533^{b} \pm 53$	$463^{b} \pm 71$
Leptin	$388^{a} \pm 92$	$90^{b} \pm 18$	$259^{a} \pm 39$
Adiponectin	$1{,}070^{a} \pm 335$	$425^{ab} \pm 143$	$460^{b} \pm 124$

[a,b]Within a gene, means lacking a common superscript differ ($P < 0.05$); n = 8.
[x,y]Within a gene, means lacking a common superscript differ ($P < 0.10$); n = 8.
[1]Results are expressed as arbitrary units ± SEM; mRNA abundance in adipose tissue was measured following a baseline period (wk 0), 12 wk after spay and food restriction to maintain BW (wk 12), and another 12 wk of ad libitum feeding and consequent BW gain (wk 24).

2006), but is rarely tested in spayed cats that are food-restricted. Lipoprotein lipase and HSL are key regulators of lipid storage and affect blood lipid concentrations. The effects of estrogen on LPL activity remain controversial. For example, Palin et al. (2003) reported decreased LPL protein expression at their greatest dose ($E_2\,10^{-7}$ mol/L) of estrogen, but increased expression at lesser doses ($E_2\,10^{-12}$ mol/L). Other research conducted in mice has shown that estrogen results in decreased LPL activity (Venkov et al., 1996). In the current experiment, wk 12 adipose mRNA abundance of HSL was unchanged, but that of LPL was decreased. However, blood lipid concentrations at 12 wk were not changed. Thus, because mRNA abundance and enzyme activities may not always agree with one another, further research is required to determine whether the decreased LPL mRNA is physiologically relevant.

One mechanism by which LPL is thought to be affected is through inhibition by proinflammatory cytokines such as TNF-α and IL-6 that are known to increase with obesity (Greenberg et al., 1992; Kern et al., 1995). Cytokine response to spaying with food restriction has not been well studied. To our knowledge, IL-6 mRNA expression has not been reported in feline adipose tissue. Elevated proinflammatory cytokine concentrations following reduced estrogen production have been reported in some human studies (Cheleuitte et al., 1998), but not others (Rogers and Eastell, 1998). Increased IL-6 expression at wk 12 in the current study suggests that estrogen withdrawal may increase proinflammatory cytokine production and is independent of BW gain. Increased IL-6 also correlates with the decreased LPL expression, supporting its inhibitory role. Tumor necrosis factor-α mRNA, however, tended to be decreased in adipose tissue at wk 12. More research is needed to determine mechanisms by which estrogen directly or indirectly affects cytokine mRNA and protein abundance.

Gonadal steroids modulate central nervous system effectors of energy homeostasis that are targets of leptin action. Whereas androgens are anabolic in nature, estrogens are catabolic and decrease food intake and BW (reviewed by Mystkowski and Schwartz, 2000). Mechanisms by which these effects occur, however, are poorly defined. Because estrogen receptors are present in adipose tissue (Pedersen et al., 1996), estrogen is thought to have a direct effect on leptin biosynthesis. Studies using rat adipocytes in culture have supported this hypothesis, demonstrating increased leptin secretion with the administration of estrogenic compounds (Machinal et al., 1999). Although BW and fat mass did not change during food restriction and spaying in the current experiment, leptin mRNA abundance was greatly decreased (approximately 23% of baseline expression) in adipose tissue. These data suggest that estrogen withdrawal and food restriction to maintain BW result in decreased leptin secretion. Because circulating leptin was not different, further study is warranted.

Effect of Ad Libitum Feeding on Body Composition and Blood Metabolites

As expected, ad libitum feeding resulted in dramatic increases in BW, body composition, and blood metabolite concentrations. Over the 12-wk period, total fat mass increased by approximately 120% compared with about 13% of lean mass. Harper et al. (2001) reported similar data (40% increase in fat mass and 10% in lean mass), suggesting that most BW gained following gonadectomy is in the form of fat. Concentrations of blood glucose, TG, and leptin were increased with BW gain. Because cats may display stress-induced hyperglycemia (Rand et al., 2002), an indicator of blood glucose concentrations over a 2- to 3-wk period (fructosamine) was measured. Although fructosamine concentrations increased with BW gain (data not shown), all values were within the normal range for cats (Bennett, 2002). Hypertriglyceridemia, which is often present in obese and type-2 diabetic cats (Hoenig et al., 2003), was also noted by wk 24. Finally, leptin concentrations tended to increase with BW gain during ad libitum feeding. Despite the lack of large changes in blood leptin concentrations, its relationship with body fat mass was highly correlated (r = 0.80). Therefore, ad libitum feeding resulted in the desired physiologic outcomes for comparison with mRNA abundance and physical activity.

Effect of Ad Libitum Feeding and BW Gain on Adipose mRNA Abundance

Altered adipose and skeletal muscle gene expression levels were expected to accompany the dramatic changes in body composition from wk 12 to 24. Decreased adipose tissue LPL mRNA abundance agrees with the results of Hoenig et al. (2006), who reported decreased LPL mRNA and enzyme activity levels in obese versus lean cats. Those researchers proposed that decreased adipose tissue LPL mRNA expression is compensated for by increased LPL expression in skeletal muscle, potentially increasing lipid deposition in skeletal muscle and contributing to insulin resistance. Adipose HSL mRNA was decreased with BW gain, which contradicts obese feline data reported by Hoenig et al. (2006), but is in agreement with Large et al. (2000) who noted decreased HSL mRNA, protein levels, and activity in obese humans. Decreased adipose HSL and LPL mRNA expression suggest a reduced activity of adipocytes with BW gain, yet the signals for such changes remain unknown.

Adiponectin mRNA abundance was decreased with BW gain, a result reported in other species, including humans (Weyer et al., 2001). Circulating adiponectin concentrations have been positively correlated with insulin sensitivity in humans and cats (Weyer et al., 2001; Hoenig et al., 2007). Although circulating adiponectin was not measured in this experiment, tissue mRNA levels suggest the potential for insulin resistance with sustained obesity. Although blood leptin tended to increase with BW gain, as reported in previous feline studies (Appleton et al., 2000), the lack of change in leptin mRNA was surprising. This discrepancy indicates that adipose tissue mRNA expression may not be indicative of plasma leptin concentrations.

Does Spaying Alter "Set Point"?

Many of the observed changes in this experiment suggest an altered "set-point" BW and metabolic activity within tissues with spaying. A "sliding set point" has been reported in seasonal animals that is dependent on photoperiod (reviewed by Rousseau et al., 2003), but has not been suggested with estrogen withdrawal. Several outcomes of this experiment, however, suggest the possibility of such a response. Briefly, adipose leptin mRNA was dramatically decreased after spaying and food restriction. Even though circulating leptin concentration was not different after 12 wk, this tissue-specific response justifies further study. Adiponectin and HSL mRNA concentrations were numerically decreased as well. Decreased adipose LPL mRNA and increased IL-6 mRNA without change in BW suggest a regulatory capacity of estrogen in these systems as well. Further support comes from the lack of expected responses to extreme BW gain during ad libitum feeding. Despite doubling fat mass from wk 12 to 24, leptin and TNF-α mRNA levels were not different from baseline as has been demonstrated in previous feline studies (Hoenig et al., 2006), and mRNA of LPL and HSL continued to be significantly decreased. Given the number of unexpected outcomes and the inability to measure cause-and-effect with such an experiment, further research is necessary to clearly identify the role of estrogen in these biological pathways and determine whether dietary intervention (e.g., those containing estrogenic compounds) may successfully minimize these changes and avoid BW gain following ovariohysterectomy.

We have presented several novel findings in food-restricted cats to maintain BW following ovariohysterectomy. During this period, voluntary physical activity was dramatically reduced, especially during the dark period. Moreover, our data suggest that estrogen withdrawal and food restriction affect the expression of several genes associated with lipid metabolism and inflammation, namely LPL, leptin, and IL-6, that may contribute to changes in appetite, blood lipid concentrations, and insulin sensitivity. Although further research is required for validation, these changes suggest that the set point of a cat may be adjusted by gonadectomy, leading to increased food intake and the physiologic outcomes that follow. By identifying changes in gene expression and physical activity of estrogen withdrawal and food restriction, potential targets for nutritional intervention or lifestyle management have been identified.

Objective—To evaluate the effect of ovariectomy on insulin sensitivity in horses and determine whether the effects of suppression of the hypothalamo-pituitary-adrenal axis differ before and after ovariectomy.

Animals—6 healthy mares.

Procedures—The horses underwent an IV glucose tolerance test (IVGTT), an insulin sensitivity test, and a dexamethasone suppression test before and 5 weeks after ovariectomy. Body weight, serum cortisol and plasma ACTH concentrations, serum insulin-to-blood glucose concentration ratios, and changes in blood glucose concentration with time after injection of glucose or insulin were compared before and after ovariectomy.

Results—The dexamethasone injection resulted in a decrease in serum cortisol concentration before and after ovariectomy. In all horses, baseline plasma ACTH concentrations were within the reference range before and after ovariectomy. For each mare, results of an IVGTT before and after ovariectomy were considered normal. No significant differences in basal blood glucose concentration or time to reach baseline glucose concentration after an IVGTT were observed. Basal serum insulin concentration and serum insulin-to-blood glucose concentration ratios were not significantly different before or after ovariectomy, nor was the mean time to attain a 50% decrease in blood glucose concentration after insulin injection.

Conclusions and Clinical Relevance—Results indicated that ovariectomy does not appear to modify dexamethasone response in horses and that it does not modify short-term measures of insulin sensitivity. Findings suggested that horses undergoing ovariectomy are not at higher risk of developing equine metabolic syndrome or hypothalamo-pituitary-adrenal axis dysfunction and associated morbidity.

Abstract

Aim: We investigated the transcervical hysteroscopy application of n-butyl-2-cyanoacrylate in the uterine tube lumen of a non-rodent animals (sheep) with fallopian tube dimensions similar those in humans.

Methods: Standard hysteroscopic procedures were performed on female Texel sheep (n = 26). The right and left ostia were identified. For each ewe, a urethral catheter (5Fr) was used for the delivery of 0.5 mL of saline or an equal volume of n-butyl-2-cyanoacrylate into the uterine tube. Following the procedure, ewes were housed with males of proven fertility for 90 days (equivalent to 5.5 estrous cycles). Postmortem (dye and burst pressure) and *in vivo* (hysterosalpingogram) testing for tube patency were both performed 90 days and 180 days following the procedure.

Results: All animals receiving the saline treatment became pregnant. Gross inspection of uterine tubes following n-butyl-2-cyanoacrylate treatment revealed no visceral adhesions or fibrosis. However, postmortem testing revealed total obstruction within the fallopian tubes. This was confirmed by hysterosalpingogram, in that iodine contrast did not escape into the abdominal cavity.

Conclusion: The cyanoacrylate promoted a reliable fallopian tube obstruction without fibrosis in an animal model exhibiting a similar tube diameter to that found in women. The technique can be evaluated for efficacy *in vivo* using hysterosalpingography.

Effects of Neodymium:Yttrium Aluminum Garnet Laser Irradiation on Endometrium and on Endometrial Cysts in Six Mares

ANTHONY T. BLIKSLAGER, DVM, LLOYD P. TATE, Jr., VMD, Diplomate ACVS, and DANIEL WEINSTOCK, DVM, PhD, Diplomate ACVS

Effects of neodymium:yttrium aluminum garnet (Nd:YAG) laser irradiation on equine endometrium were evaluated *in vitro* and in six mares with endometrial cysts. The Nd:YAG laser was applied to six endometrial sites, in each of five uterine specimens, with power densities of 5659 to 33,954 J/cm^2. Depth of tissue ablation was measured and graded on histologic sections of the tissue lesions. Power density had a significant effect on the depth of tissue ablation ($p < .001$). Grade 3 lesions (full-thickness ablation of the endometrium) were created with energy densities of 16,977 to 33,954 J/cm^2. Six mares had endometrial cysts treated by photoablation. Two of the four mares that were reproductively sound but barren, despite appropriate breeding, produced foals after treatment. One mare remained reproductively unsound after treatment, and another mare that was treated postpartum was bred successfully.

ENDOMETRIAL CYSTS CAN cause conception failure and abortion in broodmares by interfering with implantation or movement of the conceptus.[1-5] There are two forms of endometrial cysts: glandular and lymphatic.[1-6] Glandular cysts are small (several mm in diameter)[1-3,5] and may be associated with periglandular fibrosis. Glandular cysts are normal during pregnancy.[1,5,7] Lymphatic cysts are larger (1 to 20 cm in diameter)[2] and are usually found in multiparous mares older than 10 years of age.[1,4,5] Lymphatic cysts may be associated with a normal uterus or with chronic inflammation of the uterus.[1,4,5] Diagnosis of uterine cysts requires ultrasonography or endoscopy, although large cysts can be palpated per rectum.[1-5] Reported methods of treatment include electrocoagulation,[1] puncture by biopsy instrument during endoscopy,[2,4] intrauterine surgery,[1,4] and intrauterine saline infusion.[1] Endometrial cysts often recur after treatment because of failure to remove the entire cyst.[1] Complete cyst removal can be achieved by electrocoagulative and surgical techniques. These techniques are invasive, however, and technically difficult.[1] Laser treatment of equine endometrial cysts has not been reported.

The objectives of this study were: to determine the gross and histopathologic effects of neodymium:yttrium aluminum garnet (Nd:YAG) laser irradiation on uterine tissues *in vitro,* to determine the depth of tissue ablation that occurs with various power densities, and to report the use of Nd:YAG laser for the treatment of endometrial cysts in mares.

Materials and Methods

Laser

A Nd:YAG laser with a 4 m long, 2.1 mm diameter coaxial transmitting fiber was used.* The laser beam was transmitted through a 600 μm diameter fiber made of glass that was surrounded by a polyethylene tube. Carbon dioxide flowed continuously through the polyethylene tube to cool the glass fiber during activation of the laser.

Five uteri were obtained, refrigerated, and used within 24 hours. Incisions were made through the dorsal wall of

the cervix, the uterine body, and the uterine horns to expose the endometrial surface. Six sites, each separated by 1.5 cm, were selected in either the left or right uterine horn and the uterine body. In each uterus, the laser fiber was positioned perpendicular and 1 cm from the endometrial surface, giving an effective spot size of 1.5 mm diameter. A power setting of 100 watts (W) in a continuous mode was used. Exposure times, in 1 second increments, ranging from 1 to 6 seconds, were randomly selected to yield a range of power outputs from 100 to 600 joules (J). The power density (J/cm^2) applied to each site was calculated.

Each irradiated site was dissected from the uterus, pinned to a wooden tongue depressor, and fixed in 10% neutral buffered formalin. The lesion was visible grossly as a focal depigmented region or as a focal area of tissue ablation (laser crater). Fixed tissues then were sectioned with a razor blade through the center of the lesion and parallel to the plane of laser application. Tissues were embedded in paraffin, sectioned at 5 μm, and stained with hematoxylin and eosin. Thermal injury, determined by evidence of protein coagulation, charring, cavitation, and crater formation on light microscopy, was recorded. Lesions were graded as follows: grade 1, no ablation of the endometrial tissue but evidence of thermal injury to the endometrium; grade 2, ablation of the endometrial tissue (crater formation evident within the endometrium) with evidence of thermal injury to the myometrium; grade 3, ablation of endometrial and myometrial tissue (crater formation evident within the endometrium and myometrium) with evidence of thermal injury extending no further than the myometrium; grade 4, as for grade 3 except that thermal injury extended to the serosal surface.

The depth of the crater, when present, was measured using a micrometer and 4× objective on a microscope. Measurements were made from the edge of the crater to its deepest level, perpendicular to the endometrial surface. Two-way analysis of variance was used to compare the depth of tissue ablation (crater) at various energy densities and between uteri. Differences were considered significant at $p < .05$. Linear regression analysis of the depth of tissue ablation on power density was performed, and the correlation coefficient was calculated. The correlation coefficient was considered significant at $p < .05$.

Clinical cases. The medical records of mares presented for laser treatment of endometrial cysts between 1983 and 1991 were retrieved. The signalment, breeding history, method of detection of the uterine cysts (ultrasonographic or endoscopic examination), and the number, size, and location of cysts were recorded. Follow-up information on postoperative complications and reproductive performance was obtained from the owner or referring veterinarian.

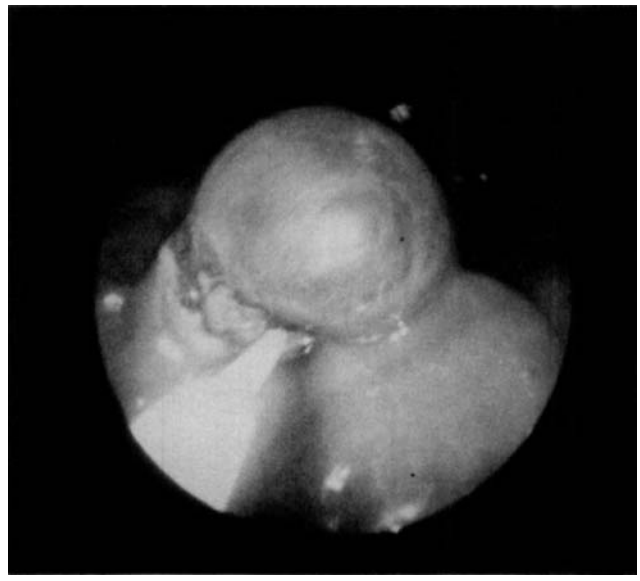

Fig. 1. Endoscopic appearance of an endometrial cyst. Nd:YAG laser (lower left) is being applied to the base of the cyst during initial blanching of the cyst membrane.

Surgical Technique

Each mare was positioned in a stocks and administered xylazine (0.3 to 0.5 mg/kg, intravenously [IV]) and butorphanol (0.02 mg/kg, IV) for sedation and analgesia. The vulva was prepared with a surgical scrub.† A 1 m flexible endoscope‡ with 2 mm and 3.4 mm biopsy channels was selected for passage of the laser fiber. Cold sterilization§ of the endoscope was performed before each use. A video camera and color monitor were coupled to the endoscope, which then was inserted into the uterus. The laser fiber was passed through the 2 mm biopsy channel until 1 to 2 cm of the fiber was visible on the monitor. The uterus then was inflated with CO_2 through the polyethylene tubing surrounding the laser fiber.

Photoablation of endometrial cysts was performed in two stages, with the laser fiber positioned 1 cm from the cyst surface. Initially, the power was set at 50 W in a continuous mode. Cysts were irradiated until the entire visible surface of the cyst was blanched (Fig. 1). Then the laser was set at 100 W in a continuous mode, and the cyst membranes were punctured. After evacuation of cyst fluid, the remaining endometrial cyst membranes were photoablated. Smoke was evacuated with a motorized, mechanical filtering device‖ attached to the 3.4 mm biopsy channel of the endoscope. Power expended for treatment

of each mare's uterus was recorded in joules, and power density was calculated. After operation, each mare was treated with procaine penicillin G (22,000 IU/kg, intramuscularly, every 12 hours) for 3 days and flunixin meglumine (1.1 mg/kg, IV) once.

Results

In Vitro Laser Application

The relationship between depth of penetration and power density is shown (Fig. 2). The grades of laser lesions produced by different power densities (J/cm^2) are recorded in Table 1. Two-way analysis of variance showed that power density had a significant effect on depth of tissue ablation ($p < .001$). In addition, there was a significant difference between the five uteri in the depth of tissue ablation obtained at the different power densities ($p < .05$).

TABLE 1. *Relationship Between Power Density (J/cm^2) and the Histologic Grade of the Lesion Produced in Five Equine Uterine Specimens*

	Energy Density (J/cm^2)					
Uterus	5659	11318	16977	22636	28295	33954
1	1	1	1	2	2	3
2	2	2	2	3	4	4
3	1	2	3	3	3	4
4	1	2	3	3	3	4
5	1	1	3	3	3	4

Lesion grade: 1 = no ablation of the endometrial tissue, but thermal injury to the endometrium; 2 = ablation of the endometrial tissue, with thermal injury to the myometrium; 3 = ablation of endometrial and myometrial tissue, with thermal injury extending no further than the myometrium; 4 = as for grade 3, except that thermal injury extended to the serosal surface.

Microscopic examination of uterine tissues showed mild autolysis, as evidenced by epithelial sloughing. Laser irradiation caused extensive thermal injury at all power densities, including tissue sections with no evidence of tissue ablation. In uterine tissues exposed to energy densities of ≥5659 J/cm^2, a laser crater was identified (Fig. 3) with evidence of thermal injury at the periphery of the crater (Fig. 4).

Clinical Cases Six mares (Table 2) had endometrial cysts treated by Nd:YAG photoablation. Based on the

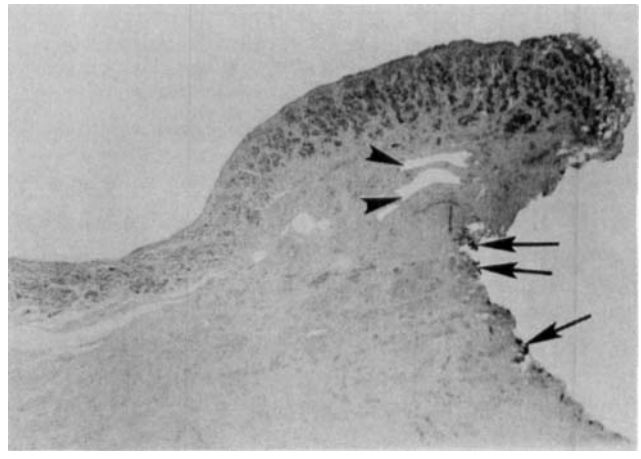

Fig. 4. Histologic appearance of the left margin of the crater in Fig. 3. Carbonization (black arrows) and cavitation (black arrowheads) are evident at the periphery of the laser crater. Tissue detail is indistinct because of protein coagulation. (H&E, ×100).

size of the cysts (0.5 to 5.5 cm diameter), and the age of the mares, the cysts were most likely lymphatic in origin.[4,5] Mares 1 through 4 were admitted for treatment of uterine cysts because of reproductive failure, despite normal cyclic activity, a uterine biopsy of grade 2 or less (Kenney system),[7] and no evidence of endometritis. For mares 1 and 2, successful conception had been determined by ultrasound examination by the referring veterinarian. Abortion or resorption of the conceptus was assumed when the mares returned to estrus. In mare 1, implantation of the conceptus adjacent to a uterine cyst was detected on ultrasound on several occasions. Mare 5 had a grade 3 uterine biopsy and chronic endometritis. *Streptococcus* spp. and fungal organisms were cultured from uterine swabs. Endometrial curettage was performed twice in an attempt to reduce infection and remove the endometrial cysts. Uterine cysts were diagnosed in mare 6 during the previous breeding season. These cysts were observed again on a postpartum ultrasound examination and had increased in size. Prophylactic removal of the endometrial cysts was recommended before breeding.

In mares 1 through 4, all uterine cysts were completely ablated. Mare 5 required two laser treatments. On the first treatment, three cysts were photoablated, but the remaining cysts could not be seem because of uterine fluid present at the time of examination. During the second treatment, three months later, small scars from the previous surgery were noted on endoscopic examination, and the remaining cysts were photoablated. In mare 6, the two largest cysts were photoablated, but the uterus could not be completely examined because of uterine fluid present at the time of examination. Two small cysts (< 1 cm) detected with ultrasonography on a subsequent examination were left untreated. No postoperative complications occurred in any of these mares.

Mare 1 produced a live foal the next season and was in foal at the time of follow-up. Mare 2 was bred during the next season, but continued to abort or resorb the conceptus, and was eventually euthanatized because of reproductive failure. Mare 3 was not bred until the second breeding season after treatment, and during the subsequent 3 years, she produced three live foals and was in foal at the time of follow-up. Mare 4 was examined endoscopically at 3 and 6 weeks after laser treatment. On both occasions, a small scar was evident at the site of the largest cyst. Despite multiple attempts, this mare did not produce a foal. Mare 5 continued to have endometritis and was used as an embryo donor for 2 years, after which she was euthanatized because of chronic laminitis. Mare 6 was bred one month after laser treatment, and produced a live foal but was not rebred.

Discussion

The Nd:YAG laser has a wavelength of 1.06 μm (near infrared spectrum) that is primarily absorbed by protein.[8] When applied to tissues, extensive penetration, reflection, and scattering of the radiation occurs, resulting in latent

TABLE 2. *Clinical Details, Date of Admission, Laser Power Used, and Outcome of Six Mares Admitted for Laser Treatment of Endometrial Cysts*

Mare	Date of Admission	Age (Years)	Breed	History	Cyst Location	No. of Cysts	Size (cm)	Laser Power (J)	Power Density (J/cm^2)	Outcome

thermal necrosis; thus the Nd:YAG laser is excellent for tissue photoablation. This effect is maximized with high power (up to 100 W), bare fiber applications.[8-10] The Nd:YAG laser beam is conducted through a flexible fiber that can be passed through an endoscope biopsy channel. This allows use of the laser within cavities that can be examined by an endoscope such as the upper respiratory tract and the reproductive tract.[8-11] A bare fiber, high power ND:YAG laser was chosen for the current study because of its ease of use in the reproductive tract in standing horses and its ability to photoablate tissues.

In vitro laser application demonstrated that increasing power density resulted in increased depth of uterine tissue ablation. One hundred watts was chosen as the power setting, because uterine cysts had been successfully ablated at 100 W in clinical cases. A grade 3 lesion was created in each uterus with power densities of 16,977 to 33,954 J/cm^2 (300 to 600 J). Because uterine cysts are superficial endometrial structures,[3-5] ablation of endometrium and myometrium (a grade 3 lesion) would be excessive. A grade 4 lesion was created in four uteri with a power density of 28,295 to 33,954 J/cm^2 (500 to 600 J). *In vivo,* a grade 4 lesion would likely result in uterine perforation because of full-thickness thermal necrosis.[8-11] These experimental observations suggest that during photoablation of endometrial cyst membranes at a power setting of 100 W, power densities of less than 16,977 J/cm^2 should be used during a single application. Cooling of tissue between applications should be allowed to prevent excessive thermal injury. During blanching of the cyst membrane, minimal Nd:YAG laser irradiation reaches the underlying endometrial tissue. After puncture and fluid evacuation of the cyst, however, laser irradiation is absorbed by the endometrium. Our inability to determine the extent of thermal injury during cyst membrane ablation prompted us to perform the *in vitro* study.

Analysis of variance showed a significant difference between depth of tissue ablation for the various laser power densities in different uteri. This suggests that different laser–tissue interactions can be expected for each horse. Reasons for this might include the age and breed of the horse, the stage of the reproductive cycle,[12] and the degree of uterine pathology, for example, the degree of fibrosis. There also may be different laser–tissue interactions between refrigerated uterine tissue and uterine tissue in living horses. Absorption of Nd:YAG laser irradiation in living tissue would likely be less, because the blood-filled vessels would tend to insulate tissue because Nd:YAG laser irradiation is poorly absorbed by water.

Clinically, the Nd:YAG laser has been shown to be beneficial for treatment of pharyngeal cysts in horses.[8,10] Initial blanching of cysts at a power setting of 50 W ensures absorption of radiation by protein within the cystic fluid without rupturing the cyst. This results in thermal damage to the inner lining, and decreases recurrence.[8,10] The cyst then is punctured to evacuate the fluid, and the cyst lining tissue is then photoablated at 100 W. In the current study, endometrial cysts were photoablated successfully whenever they were adequately visualized. In two mares, some of the cysts were not seen because of intrauterine fluid. Based on these experiences, the authors recommend evacuation of uterine fluid before starting laser treatment. Follow-up endoscopic examination of mares 5 and 6 showed that sites of laser cyst ablation remained as small scars.

Recurrence of endometrial cysts has occurred with techniques that incompletely remove the cystic structure, including puncture by biopsy instrument, needle aspiration, and endometrial curettage.[1,2,4] In mare 5, endometrial curettage had failed to remove the endometrial cysts. Complete removal of cysts has been achieved with intrauterine surgery and electrocoagulative surgery.[1] Previously reported intrauterine surgical techniques required general anesthesia and laparotomy, and electrocoagulative surgery required use of instrumentation that was difficult to manipulate.[1] In six mares where electrocoagulative surgery was used, an 8 cm diameter cyst was too large to remove by this technique.[1] Laser ablation of cysts compares favorably to these techniques because complete cyst destruction is possible, and the technique is easy to perform. Although the largest cyst that was ablated in the current study was 5.5 cm in diameter, there is no indication based on our clinical experience that larger endometrial cysts could not be treated with the Nd:YAG laser. Based on reports of laser treatment of pharyngeal cysts, cyst recurrence is unlikely.[8,10]

Mares 1 through 4 met previous criteria for reproductive failure associated with endometrial cysts.[1] These criteria were failure to conceive despite appropriate breeding, an absence of endometritis, a uterine biopsy grade not higher than grade 2, and the presence of endometrial cysts.[1] In the current report, mare 1 had ultrasonographic evidence of interference between the conceptus and an endometrial cyst. Of these four mares, mares 1 and 3 produced foals, suggesting that photoablation of endometrial cysts can result in successful conception.

Mare 5 had a poor prognosis for future reproductive performance because of evidence of a fungal endometritis and a grade 3 uterine biopsy. This mare was referred specifically for laser treatment of endometrial cysts in the hope that cyst ablation, particularly at the internal cervical os, might enable successful treatment of the endometritis. Mare 6 was treated prophylactically. This mare may have been bred successfully without treatment of cysts. Others have reported that some mares with endometrial cysts can carry pregnancies to term.[1] Therefore, mares probably should meet the criteria described earlier for reproductive failure associated with endometrial cysts before treatment

is considered. Laser treatment of mare 6 did not have a detrimental effect on reproductive performance, and breeding as early as one month after treatment is apparently feasible. Treatment during anestrus is suggested, however, so that lased tissue has time to heal before the breeding season. In addition, inflammation associated with laser treatment should be allowed to subside before breeding.

Laser ablation of endometrial cysts should be performed with a series of low-power density applications ($\leq$11,318 J/cm^2) to prevent excessive ablation of uterine tissue. With appropriate application and case selection, photoablation with a Nd:YAG laser is an effective method of treating endometrial cysts and may result in successful conception. Further studies on Nd:YAG laser interactions with uterine tissues *in vivo* are warranted. Treatment of a large number of mares, with long-term follow-up, is also needed to fully evaluate the efficacy of laser photoablation of endometrial cysts.

CHAPTER 1—INTRODUCTION

GENERAL

The Bureau of Land Management (BLM) is responsible for the protection, management and control of wild free-roaming horses and burros (WH&B). Under the Wild Free-Roaming Horses and Burros Act (WFRHBA), WH&B are considered an integral part of the national system of public lands in the areas where they were found in 1971. The BLM's goal is to manage healthy WH&B populations on healthy rangelands. To achieve this goal, the BLM designates Herd Management Areas (HMAs) for the long-term maintenance of WH&B herds and collects data about the animals and their habitat. The BLM also prescribes management to assure WH&B populations are in balance with other uses of the public lands and that a thriving natural ecological balance (TNEB) is achieved and maintained. Activities are carried out with the objective of maintaining free-roaming behavior and at the minimum feasible level of management necessary to attain the objectives identified in approved land use plans (LUPs) and Herd Management Area Plans (HMAPs).

1.1 PURPOSE

This handbook describes the authorities, objectives, policies and procedures that guide the management of WH&B on the public lands administered by the BLM.

1.2 OBJECTIVE

The objective of this handbook is to provide guidance for the protection, management and control of WH&B in accordance with the 1971 WFRHBA, as amended, and the implementing regulations in 43 Code of Federal Regulations (CFR) 4700.

CHAPTER 2—LAND USE PLANNING

GENERAL

Section 202(a) of the 1976 Federal Land Policy and Management Act (FLPMA) requires the Secretary to develop, maintain, and when appropriate revise LUPs that provide (by tracts or areas) for the use of the public lands. The responsible BLM official shall follow the established LUP procedures in 43 CFR 1600, associated BLM manual sections and policy for fulfilling the planning requirements prescribed in the statute.

LUPs are the basis for every on-the-ground management decision that the BLM makes. LUPs establish goals and objectives (desired outcomes), identify the management actions needed to achieve the desired outcomes, and identify allowable uses of the public lands.

2.1 LAND USE PLAN DECISIONS

LUP planning requirements for the WH&B program are applicable to all BLM LUP documents, including Management Framework Plans (MFPs) and Resource Management Plans (RMPs).

2.1.1 Comparability Consideration

Under 43 CFR 4700.0-6(b), WH&B shall be considered comparably with other resource values in the formulation of LUPs. This means WH&B are to be considered in the same manner as other resource values (e.g., cultural, historic, scenic, rangelands, timber, and minerals). WH&B are a resource value, as opposed to a land use (e.g., livestock grazing or timber harvest).

2.1.2 Herd Areas

Herd areas (HAs) are limited to areas of the public lands identified as habitat used by WH&B at the time that the WFRHBA passed (December 15, 1971). When preparing a LUP, identify the HAs (in whole or in part) which will not be managed as HMAs and explain the reasons they will not be managed for WH&B.

HA boundaries can be adjusted through a LUP when the current boundary does not correctly portray where WH&B were found in 1971 based on well-documented historical data. Existing herd areas where all animals were privately-owned (claimed during the claiming period) shall be dropped from HA status in a LUP.

Under 43 CFR 4710.2 and to assure transparency regarding the disposition of HAs, the authorized officer shall permanently maintain a record regarding the location of all HA boundaries and explanations of any changes in field office (FO) files.

2.1.3 Herd Management Areas

HMAs shall be designated in those HAs within which WH&B can be maintained over the long term in LUPs. For each HMA designated within the planning area, the LUP should identify the following:

- The HA(s) that contain the HMA.

- The initial and estimated herd size that could be managed while still preserving and maintaining a TNEB and multiple-use relationships for that area.

- The guidelines and criteria for adjusting herd size.

LUPs should also identify:

- The HMAs to be managed for non-reproducing wild horses to aid in controlling on the range population numbers and the criteria for their selection (16 United States Code (USC) § 1333(b)(1)). See Chapter 4 (Population Management). Examples of criteria that could be used to select HMAs for management of non-reproducing wild horses include: no special or unique herd characteristics, low ecologic condition, limited public land water, and reliance on private water.

- The management tools to control population size within AML and to extend (reduce) gather frequency.

2.1.4 Herd Areas Not Designated as HMAs

Where appropriate, the LUP may include decisions not to manage WH&B in all or a part of an HA. An example is intermingled and unfenced private lands within HAs where the landowners are unwilling to make them available for WH&B use, or the animals present at that time were later found to be claimed domestic horses (or burros). Another example would be where essential habitat components (forage, water, cover and space) are unavailable or insufficient to sustain healthy WH&B and healthy rangelands over the long term.

2.1.5 Changes to HA or HMA Boundaries

Decisions to change HA boundaries, to designate HMAs for the maintenance of WH&B, or to remove all or a portion of an area's designation as an HMA must be made through a LUP amendment, revision or new RMP (43 CFR 4710.1 and H-1601-1: Land Use Planning Handbook).

HMA boundaries may be changed within HAs through the LUP process to facilitate WH&B management or mitigate unacceptable impacts to other resources.

An area may lose its designation as an HMA when WH&B cause unacceptable impacts to other resource values, or conditions change and one or more of the four essential habitat components are not present in sufficient quantities to sustain WH&B use over the long term. Similarly, if conditions change, all or part of an HA may be reconsidered for designation as an HMA through LUP. See Chapter 3 (Habitat Management).

2.1.6 Wild Horse and/or Burro Ranges

An HMA may be considered for designation as a WH&B Range to be managed principally, but not necessarily exclusively, for WH&B. Criteria for consideration as a WH&B Range should include the presence of one or more of the following: unique herd characteristics, outstanding viewing opportunities, unique landscape, or significant historical or cultural features (H-1601-1: Appendix D). The authorized officer, currently only the Director or Assistant Director (AD) (refer to BLM Manual 1203: Delegation of Authority), may establish a WH&B Range after a full assessment of the impact on other resources through the LUP process.

2.2 GRAZING AUTHORIZATIONS WITHIN HMAs

Domestic horses and burros may not graze under permits or leases within HMA boundaries (43 CFR 4710.5(b)). If necessary to provide habitat for WH&B, to implement herd management actions, or to protect WH&B from disease, harassment or injury, the authorized officer may close areas of the public lands to grazing use by all or a particular kind of livestock (43 CFR 4710.5(a)).

Closure to livestock grazing may be temporary or permanent (43 CFR 4710.5(c)). Prior to issuing a final decision to permanently close an area to livestock grazing use, a LUP amendment should be completed. Completion of site-specific environmental analysis and issuance of a proposed and final decision pursuant to 43 CFR 4160 (2005) is also required.

2.3 OTHER PERMITTED ACTIVITIES

2.3.1 Commercial Recreation Use

Proposals for commercial recreational use of the public lands should be evaluated through the appropriate BLM permitting process. Permits should stipulate the safeguards necessary to protect the health and welfare of WH&B, particularly before, during and immediately following the peak foaling period (e.g., generally March – June). See Chapter 4 (4.4.4).

Proposals for motor vehicle racing, air racing, or other potentially intrusive activities have potential to harass or harm WH&B. Permit authorizations should contain provisions to minimize impacts to WH&B from these activities. Should adequate safeguards prove impractical, permits should not be approved (refer to BLM Manual Section 2930 and H-2930-1: Recreation Permit Administration).

2.3.2 Energy and Minerals Exploration and Development

The health and welfare of WH&B should be considered during project planning for hard-rock mining or oil and gas exploration and development; non-mineral sales such as gravel; or wind or solar energy development proposals. Specific mitigation measures will be identified through a site-specific environmental analysis and decision process in accordance with the 1969 National Environmental Policy Act (NEPA). Mitigation measures will be implemented through applicable permits.

2.4 LAND USE PLAN GOALS AND OBJECTIVES

LUPs normally contain general habitat and population management goals and objectives. LUPs may also include the management requirements or actions necessary to make progress toward attainment of Land Health Standards and to preserve and maintain a TNEB and multiple-use relationship on the public lands.

2.4.1 Habitat and Population Management

Habitat or population management and monitoring objectives regarding the management of a specific HMA or complex of HMAs are normally identified in a Herd Management Area Plan (HMAP) rather than a LUP.

2.5 IMPLEMENTATION DECISIONS

Implementation decisions make progress toward achieving LUP goals and objectives and may include:

- Establishing or adjusting appropriate management levels (AMLs) based on monitoring and evaluation, including the population range within which the herd size will be allowed to fluctuate.
- Identifying and setting objectives for herd composition, animal characteristics and habitat development needs (e.g., HMAPs).
- Specific habitat improvement projects (e.g., construction, modification, or removal of fences; water development construction/reconstruction or removal; or re-vegetation projects).
- Site-specific population management actions (e.g., decisions to gather/remove excess WH&B, apply fertility control, or adjust age or sex ratios).

2.5.1 Appropriate Management Level (AML) Adjustments

AML may be adjusted (either up or down) through a site-specific environmental analysis and decision process (NEPA). An analysis under NEPA is also required to establish a population range (upper and lower limit) for AMLs initially established as a single number. Development of a LUP amendment or revision is not generally required.

2.5.1.1 AMLs Established in LUPs

- When AML is established in a LUP, follow the process outlined in the LUP to adjust AML.

- When the LUP does not outline a process for AML adjustment, the LUP may need to be amended or revised to adjust AML.

2.5.1.2 AMLs Established through Implementation Decisions

See Chapter 4 (4.2.2).

2.5.2 Herd Management Area Plans

Herd Management Area Plans (HMAPs) are prepared under 43 CFR 4710.3-1. HMAPs establish short- and long-term management and monitoring objectives for a specific WH&B herd and its habitat. HMAPs also identify the actions to be taken to accomplish herd and habitat management objectives. An HMAP assists the authorized officer in tracking progress toward achieving LUP goals.

HMAPs tier to and must be in conformance with the applicable LUP. If the proposed management strategy is not consistent with the LUP, then the LUP should be amended, or the proposal should be modified or rejected.

HMAPs may be prepared for a single HMA or a complex of adjacent HMAs where animal interchange occurs. When two or more jurisdictions have management responsibility for portions of a single HMA or an HMA complex, BLM will designate one field office with the lead responsibility for development of the HMAP and management of the HMA or complex. When a WH&B herd is dependent on the habitat within a BLM HMA and an adjacent U.S. Forest Service (USFS) Wild Horse Territory (WHT), the agencies should jointly determine lead responsibility for development of the HMAP and management of the herd and habitat.

2.6 NOTICES, CONSULTATIONS AND HEARINGS

2.6.1 Agency Consultation and Public Involvement

See BLM Manual Section 4710.25.

2.6.2 Hearings

See BLM Manual Section 4740.3.

CHAPTER 3—HABITAT MANAGEMENT

GENERAL

Habitat for WH&B is composed of four essential components: forage, water, cover, and space. These components must be present within the HMA in sufficient amounts to sustain healthy WH&B populations and healthy rangelands over the long term. If they are not present in sufficient amounts, the authorized officer should consider amending or revising the LUP to remove the area's designation as an HMA. If the decision is made to return a designated HMA to HA status, the total population of WH&B should then be gathered and removed. See BLM Manual Section 4710.3.

A recurring pattern of WH&B movement out of the HMA to access forage, water, or thermal or hiding cover is an indication that year-long WH&B use cannot be sustained. If one or more of the key habitat components is missing, the HMA should be considered as unsuitable for year-long use. In these situations, the authorized officer should consider removing the area's designation as an HMA through LUP. An exception would be two or more HMAs which adjoin and are managed as a complex of HMAs, or HMAs which adjoin USFS WHTs that can be managed as a complex.

3.1 FORAGE (VEGETATION)

Forage (vegetation) is one of the essential components of WH&B habitat. The authorized officer should determine whether vegetation provides sustainable forage (and cover) for the animals. Vegetation should be managed within each HMA in a manner that achieves and maintains a TNEB and assures significant progress is made toward achieving the Standards for Land Health and other site-specific or landscape-level objectives.

3.2 WATER

An adequate year-round quantity and quality of water must be present in the HMA to sustain WH&B numbers within AML. If baseline information concerning access to and availability of water does not exist, then a public land water inventory should be conducted.

If privately-owned water is essential to sustaining WH&B populations within HMAs, cooperative agreements with the owners or acquisition of water rights should be considered. If agreement cannot be achieved with private water owners, or if public land water cannot be developed and maintained, one of the following should occur:

- AML should be adjusted based on the available public land water within the HMA boundary.

- The authorized officer should amend or revise the LUP to remove the area's designation as an HMA.

3.3 COVER (VEGETATION) AND SPACE

The terrain and vegetation are needed to provide WH&B with escape (hiding) cover and shelter from the prevailing weather. (Vegetation also provides sustainable forage. See 3.1 above). WH&B require sufficient space to allow the herd to move freely between water and forage within seasonal habitats. Cover and space are interrelated. If the HMA has barriers preventing free movement of WH&B throughout the HMA or between forage and water, it would not have sufficient cover and space. Barriers can be natural (e.g., rock rims, rivers) or human-induced (e.g., fences, highways).

3.4 HABITAT IMPROVEMENT PROJECTS

3.4.1 Nonstructural Improvements

Nonstructural improvement projects such as seeding, prescribed fire, emergency fire rehabilitation or shrub and tree removal have potential to increase the forage available for WH&B use and to improve habitat conditions. They may also cause grazing animals to concentrate their use within the project area. As a result, it may be necessary to close these areas to grazing until vegetation management objectives are achieved.

Before making the decision to exclude an area from grazing use, the authorized officer should first take a hard look at alternatives to fencing. These alternatives could include:

- Reduce WH&B populations to the AML lower limit.
- Reduce WH&B to a number below the AML lower limit (based on the available forage and water).
- One of the above, in combination with closing the area to domestic livestock use (in whole or in part).
- Use of mineral supplements to modify distribution.
- Restrict or eliminate access to selected water sources.

If the authorized officer determines fence construction is necessary, the fences should be designed to maintain WH&B access to critical water sources. Fences should then be removed once objectives have been achieved.

3.4.2 Structural Improvements

Construct and maintain structural improvement projects (e.g., fences, cattle guards, or water developments) in a manner that protects the wild, free-roaming nature of WH&B and provides for normal herd distribution and movement as well as genetic interchange.

While some projects might increase the forage, cover, or water available for WH&B, others might negatively impact individual animals or entire populations:

- Fences and cattle guards might restrict seasonal WH&B movement or use of critical escape (hiding) or thermal cover, key spring-summer-fall-winter use areas, or critical water sources.

- Water development projects might encourage use outside the HMA or concentrate use in sensitive areas.

Existing projects that negatively impact WH&B should be considered for removal or modification through coordinated activity plans. Proposed projects should be analyzed and mitigation proposed to minimize adverse impacts to WH&B where possible.

3.4.2.1 Existing Fences and Cattle Guards

Existing fences and cattle guards with negative impacts to WH&B should be reviewed to determine:

- If the project is still needed; or
- Whether the project can be modified to minimize impacts to WH&B.

Possible fence or cattle guard modifications could include:

- Make fences open-ended allowing WH&B movement around the ends.
- Construct large gates or sections of "let-down" fence, or consider the use of electric take-down fence where feasible, to allow movement when fences are not needed for livestock control.
- Weld rebar strips between cattle guard grates; or
- Replace the cattle guard with a gate, if possible.

3.4.2.2 Proposed Fences and Cattle Guards

Fencing within an HMA should be done only after the impacts are carefully analyzed through the NEPA process. If fences and cattle guards are essential for proper resource management, they should be constructed with particular attention to location and design. Avoid locating fences across migration routes, to prevent WH&B (or livestock) concentration, or the unintended trapping or death of WH&B.

3.4.1.3 Existing Water Developments

Consistent with resource management objectives, existing projects may be modified to provide WH&B with access to water through one or more of the following methods:

- Piping water to a trough away from the source.
- Piping water to a trough outside an exclosure.
- Retaining a portion of the source outside the exclosure.

3.4.1.4 Proposed Water Developments

Water sources may be excluded from use by WH&B to protect the water source, the associated riparian area, and to maintain or improve the quality and quantity of water. Where possible, projects should be designed to provide WH&B with access to water as described in 3.4.1.3 above.

Fences constructed in proximity to major WH&B water sources and smaller riparian pastures or exclosures should be constructed with a top rail composed of pipe or wooden poles. The top rails provide a visual barrier to prevent WH&B from entering the exclosure and becoming trapped. Project design may also consider the use of specialized gates (e.g., finger gates) to allow any WH&B entering an exclosure to exit safely.

Reservoirs and similar water sources should be designed and maintained with gently sloping (rather than steep) sides to avoid trapping foals.

Where WH&B are, or may become, dependent upon mechanically provided water, the authorized officer shall assure that alternative sources of known and accessible water are available to WH&B in the event of a system failure of a well, storage tank, pipeline, trough, or float device.

Actions to assure water is available to WH&B may include:

- Entering into Cooperative Range Improvement Agreements (Form 4120-6) whose terms and conditions require water to be made available to WH&B and wildlife.

- Using WH&B program funding (in whole or part) for construction and/or maintenance of a well, spring development, catchment, pond, or other permanent water improvement providing WH&B with access to water on public land.

- Acquiring the necessary water rights in order to provide and maintain access to water sources. Refer to BLM Manual 7250 (Water Rights).

CHAPTER 4—POPULATION MANAGEMENT

GENERAL

Under the 1971 WFRHBA, WH&B are to be managed in a manner designed to achieve and maintain a thriving natural ecological balance and protect the range from the deterioration associated with WH&B overpopulation.

4.1 MANAGEMENT REQUIREMENTS

4.1.1 Self-Sustaining

WH&B shall be managed as self-sustaining populations of healthy animals in balance with other uses and the productive capacity of their habitat. Some selected HMAs may be managed for non-reproducing wild horses to aid in controlling on-the-range population numbers (see 4.5.4).

4.1.2 Free-Roaming Behavior

In accordance with 43 CFR 4700.0-6(c), management activities affecting WH&B shall be undertaken with the goal of maintaining free-roaming behavior.

4.1.3 Constraints on Management

Management of WH&B on the public lands is limited to herd areas (HAs), consistent with the WFRHBA (16 USC § 1339) which states: “Nothing in this Act shall be construed to authorize the Secretary to relocate wild free-roaming horses or burros to areas of the public lands where they do not presently exist.”

Consistent with 43 CFR 4710.3-1, herd management areas (HMAs) shall be established for the maintenance of WH&B herds. In delineating each HMA, the authorized officer shall consider the appropriate management level for the herd, the habitat requirements of the animals, and the relationships with other uses of the public and adjacent private lands, and the constraints contained in § 4710.4.

4.1.4 Minimum Feasible Level of Management

As required in 43 CFR 4710.4, management shall be at the minimum level necessary to attain the objectives identified in approved LUPs and HMAPs.

1. Limit population management actions by:

    a. Establishing AML as a population range within which herd size will be allowed to fluctuate.

    b. Evaluating HMAs that require frequent emergency or nuisance removals due to inadequate habitat (e.g., limited availability of forage or water) for the possible removal of the area’s designation as an HMA through LUP.

2. It is not consistent with management at the minimal level to provide supplemental feed or rely on water developments that require frequent maintenance. It may, however, be appropriate to provide water in temporary emergency situations.

4.1.5 Thriving Natural Ecological Balance (TNEB)

Consistent with 43 CFR 4700.0-6, WH&B shall be managed in balance with other uses and the productive capacity of their habitat (i.e., WH&B will be managed to achieve and maintain a thriving natural ecological balance (TNEB) and multiple use relationships on the public lands).

The WFRHBA requires the BLM to manage horses in a manner that is designed to achieve and maintain a thriving natural ecological balance on the public lands (16 USC § 1333(a)). *See also Animal Protection Institute of America*, 109 IBLA 112, 115 (1989) ("…the 'benchmark test' for determining the suitable number of wild horses on the public range is 'thriving natural ecological balance'…") (*Dahl v. Clark*, 600 F. Supp. 585, 594 (D. Nev. 1984)).

To achieve a TNEB on the public lands, WH&B should be managed in a manner that assures significant progress is made toward achieving the Land Health Standards for upland vegetation and riparian plant communities, watershed function, and habitat quality for animal populations, as well as other site-specific or landscape-level objectives, including those necessary to protect and manage Threatened, Endangered, and Sensitive Species (TES). WH&B herd health is promoted by achieving and maintaining TNEB.

4.2 ESTABLISHING THE APPROPRIATE MANAGEMENT LEVEL

4.2.1 AML Definition

The appropriate management level (AML) shall be expressed as a population range within which WH&B can be managed for the long term. AMLs previously established as a single number will be modified to include an upper and lower limit. For reporting purposes, the upper limit of the AML range will be used.

AML applies to the number of adult wild horses or burros to be managed within the population and does not include current year's foals. All WH&B one year of age and older are considered adults (a foal is considered one year of age on January 1 of the year following its birth).

The AML upper limit shall be established as the maximum number of WH&B which results in a TNEB and avoids a deterioration of the range. This number should be below the number that would cause rangeland damage (refer to *Animal Protection Institute of America v. Nevada BLM*, 118 IBLA 63, 75, (1991)).

The AML lower limit shall normally be established at a number that allows the population to grow (at the annual population growth rate) to the upper limit over a 4-5 year period, without any interim gathers to remove excess WH&B. Some HMAs may require more frequent removals to maintain population size within AML. For HMAs that require more frequent gathers, the authorized officer should consider management options which would either extend the gather

cycle or broaden the AML range; amend or revise the LUP to remove the area's designation as an HMA; or manage the HMA for non-reproducing wild horses.

4.2.2 Establishing or Adjusting AML

An interdisciplinary and site-specific environmental analysis and decision process (NEPA) with public involvement is required to establish or adjust AML.

4.2.2.1 Establishing AML

When establishing AML, the analysis shall include an in-depth evaluation of intensive monitoring data or land health assessment. Intensive monitoring data shall include studies of grazing utilization, range ecological condition and trend, actual use, and climate (weather) data. Population inventory, use patterns and animal distribution should also be considered. A minimum of three to five years of data is preferred. Progress toward attainment of other site-specific and landscape-level management objectives should also be considered. See Appendix 3 (AML Establishment and Adjustment).

4.2.2.2 Evaluation and Adjustment of AML

In-depth AML evaluations should be completed when review of resource monitoring and population inventory data indicates the AML may no longer be appropriate. The following should be considered when evaluating AML:

- Changes in environmental conditions which may have occurred since the AML was established. Changing environmental conditions could include drought, wildfires, noxious weed infestations, effect of varying numbers of WH&B on forage utilization or range ecological condition/trend, an increase or decrease in the available forage, changes in livestock management, etc.

- The presence of any newly listed Threatened, Endangered or Sensitive Species (TES).

- Any additional resource monitoring, population inventory or other relevant data collected since AML was established.

For additional information refer to Appendix 3 (AML Establishment and Adjustment) and BLM Manual Section 4720.3.

4.2.3 WH&B Animal Unit and Animal Unit Month

Wild horses, one year of age or older, count as one (1) Animal Unit (AU) and burros one year of age and older count as 0.5 AU. One Animal Unit Month (AUM) is the amount of forage necessary to sustain one adult horse or two adult burros for one month (or approximately 800 pounds of air dried forage).

4.2.4 Forage Allocations for WHB

The amount of forage available to allocate to WH&B shall be determined through in-depth evaluation of resource monitoring data and following a site-specific environmental analysis and decision process. Forage for WH&B (AUMs) is allocated based on the AML upper limit.

4.3 DETERMINATION OF EXCESS

Before issuing a decision to gather and remove animals, the authorized officer shall first determine whether excess WH&B are present and require immediate removal. In making this determination, the authorized officer shall analyze grazing utilization and distribution, trend in range ecological condition, actual use, climate (weather) data, current population inventory, wild horses and burros located outside the HMA in areas not designated for their long-term maintenance and other factors such as the results of land health assessments which demonstrate removal is needed to restore or maintain the range in a TNEB.

The term "excess animals" is defined as those animals which must be removed from an area in order to preserve and maintain a thriving natural ecological balance and multiple-use relationship in that area (16 USC § 1332(f)(2)). This definition underscores the need to remove excess animals before damage to the range begins to occur.

4.4 PARAMETERS FOR POPULATION MANAGEMENT

4.4.1 Age Structure and Sex Ratio

Age structure and sex ratio influence herd health, social interactions, and population growth rates of reproducing WH&B herds. A herd's age structure and sex ratio may have been altered by previous selective removal policies or natural mortality and should be estimated from the best available data (e.g., capture records, preparation records, and final gather reports). Most populations will have representatives from each age class, and rapidly growing populations will have a greater proportion of younger WH&B. WH&B populations will produce roughly equal numbers of males and females over time.

In order to maintain the desired age structure and sex ratios, consider retaining male and female animals from each age group (0-4, 5-9, 10-15, 15+ years of age) following a removal operation. If specific age structure and sex ratio objectives are not established for an HMA or complex of HMAs, a desired post-gather age structure and sex ratio should be established during the pre-gather planning and analysis process. These objectives should be consistent with the selective removal criteria outlined in BLM Manual Section 4720.33 and the AML lower limit.

The authorized officer should consider alternatives which would manage WH&B herds for a sex ratio with a female component of less than or equal to 50 percent, to reduce population growth rates and extend the gather cycle. Opportunities to manage sex ratios as a tool to slow population growth rates are discussed later in this chapter.

4.4.2 Selective Removal

Selective removal and release of animals back to the range should be conducted to achieve AML, and the age structure and sex ratio objectives established for the specific HMA or complex of HMAs. In the absence of specific age structure or sex ratio objectives for the HMA or complex, see BLM Manual Section 4720.33.

4.4.3 Population Growth Rates

Population growth rates represent the net difference between births and deaths over time. Population growth rates can be highly variable and influenced by habitat quality, forage production, water availability and other factors. Data from recent gathers and population estimates derived from aerial surveys are used to determine population growth rates. The annual growth rate from Year 1 to Year 2 is calculated as follows:

Population on 2/28 (Year 2) – Population on 2/28 (Year 1)
÷ Population on 2/28 (Year 1) ×100 = Percent Annual Growth Rate

The same formula can be used to calculate growth over a period of several years (e.g., between aerial population surveys which are normally conducted at 3-4 year intervals).

Significant variation from historical growth rates may indicate that either immigration into the HMA or migration out of the HMA is occurring.

4.4.4 Foaling Period

Foaling period can be documented for each population (individual HMA or HMA complex) through direct observation. The capture of wild horses by using a helicopter to herd the animals is prohibited during the foaling period, which is defined as six weeks on either side of the peak of foaling to assure that young foals are mature enough to be able to remain with their band during gather activities. This period is generally March 1 to June 30 for most wild horse herds. Helicopters may be used year-round in the removal of burros. See BLM Manual Section 4740.1.

The capture of wild horses and burros by using bait (e.g., food, water, salt or sexual attraction) to lure animals into a trap may be used year-round.

Population surveys or distribution flights involving fixed-wing aircraft may be conducted during the foaling period. The use of helicopters for these activities during this time should be evaluated on a case-by-case basis.

4.4.5 Gathers and Gather Cycles

The gather cycle is the interval between gathers. Gather frequency is a function of the AML range, population growth rates and other environmental factors. Once AML is achieved, gathers to remove excess WH&B should be planned to occur at intervals of approximately 4 to 5 years to maintain population size within AML.

4.4.6 Genetic Diversity

Reproducing WH&B herd health is dependent, in part, on maintaining desirable genetic diversity (avoiding inbreeding depression).

4.4.6.1 Baseline Genetic Diversity

Baseline genetic diversity will be determined for all WH&B herds. Once a baseline is established, additional samples will be collected to reassess genetic diversity every other gather (e.g., every 6-10 years). If testing indicates diversity is less than desired, the herd should be reassessed more frequently (e.g., every gather).

In the past, genetic diversity was assessed by evaluating blood samples from the herd. Hair samples are now used to assess genetic diversity. Procedures for collecting and processing WH&B hair samples are described in Appendix 1 (Genetics Data and Hair Sample Collection Instructions). A report assessing genetic diversity is developed for each set of samples from an HMA.

Baseline data can be compared between adjacent HMAs to determine if the WH&B herd is isolated, or if genetic material is being exchanged between reproducing herds as part of a larger population of WH&B. Movement of WH&B from one HMA to another may enhance genetic diversity.

4.4.6.2 Interpreting Genetics Data

Measures of individual animal and population-wide genetic diversity are based on the number of individuals sampled within each HMA or complex. The most important measure of genetic diversity is Observed Heterozygosity (Ho). The observed heterozygosity is a measure of how much diversity is found, on average, within individual animals in a WH&B herd and is insensitive to sample size, although the larger the sample, the more robust the estimate.

Population-wide measures for the presence of genetic variants and the effective number of alleles provide information about changes in a herd's diversity, now and in the future. Other measures provide a comparison of the herd's genetic similarity to domestic horse breed types. All measures are compared to values derived from domestic horse breeds and to WH&B herds which have already been sampled.

Values below the mean for feral populations are an indication that the WH&B herd may have diversity issues. Herds with observed heterozygosity values that are one standard deviation below the mean are considered at critical risk. For DNA-based (hair) samples this value is 0.66, and the value is 0.31 for blood samples.

Few herds sampled to date show values below the feral mean. Those with values below the feral mean tend to be herds with small population size, which are the most at-risk for inbreeding. There is no specific diversity value that is a clear indicator of imminent inbreeding risk. The lower the genetic variation, the greater the risks for inbreeding-related impacts to the WH&B

herd. Mitigation to address or resolve genetic diversity concerns should be considered using the recommendations in the genetics report as a starting point.

4.4.6.3 Herd Size

A minimum population size of 50 effective breeding animals (i.e., a total population size of about 150-200 animals) is currently recommended to maintain an acceptable level of genetic diversity within reproducing WH&B populations (Cothran, 2009). This number is required to keep the rate of loss of genetic variation at 1 percent per generation. Animal interchange between adjacent HMAs with smaller population sizes may reduce the need for maintaining populations of this size within each individual HMA. Research has not yet established a recommended minimum breeding herd size for burros.

4.4.6.4 Management Actions

If the recommended minimum wild horse herd size cannot be maintained due to habitat limitations (e.g., insufficient forage, water, cover and/or space) or other resource management considerations (e.g., T&E species), a number of options may be considered as part of an appropriate site-specific NEPA analysis to mitigate genetic concerns:

- Maximize the number of breeding age wild horses (6-10 years) within the herd.
- Adjust the sex ratio in favor of males to increase the number of harems and effective breeding males.
- Introduce 1-2 young mares every generation (about 10 years), from other herds living in similar environments.

If wild horse herd size in small, isolated HMAs is so low that mitigation is not feasible, consideration should be given to managing the HMA for non-reproducing wild horses or to removing the area's designation as an HMA through LUP.

4.4.7 Herd Social Structure

Some management actions (e.g., sex ratio adjustments to favor stallions) may affect social structure and herd interactions (e.g., band size).

4.4.7.1 Wild Horses

The social structure of most wild horse herds consists of breeding and bachelor bands. Breeding bands or harems usually consist of a dominant stallion, lead or dominant mare(s), a group of breeding mares, and associated foals and yearlings. Most wild horses breed and foal in the spring of the year. Bachelor bands consist of various aged males that either have not yet established their own harem or have lost their mares. The composition of bachelor bands varies considerably throughout the year. In most breeding bands, male foals leave the band at 1 or 2 years of age and generally join bachelor bands.

Although wild horse bands tend to use the same habitat areas (home ranges) from year to year, they are not territorial and do not defend preferred habitat areas. As a result, bands often graze

and water near each other, and there may be movement of mares between bands. This, in combination with the periodic displacement of the dominant stallion and removal or death of other horses, results in a very fluid social structure in most herds. These factors are beneficial in enhancing genetic diversity.

4.4.7.2 Wild Burros

Wild burros do not form breeding bands. There are no strong individual bonds other than jenny-foal relationships. Wild burros present themselves as single animals, all-male groups, all-female groups, jenny-foal groups, or mixed groups. All of the groups are variable and their composition may change at any time. This loose social structure, where all animals are potential breeding partners, maximizes genetic diversity in small or dispersed burro populations.

Some of the older jacks establish a breeding territory but do not prevent other males from entering this area unless there is an estrous female present. It is common for males to roam freely throughout their habitat and breed upon encountering an estrous female. Large male groups may form in the vicinity of an estrous female, and it is normal for the jenny to have multiple breeding partners.

In dispersed populations in a desert environment, breeding efficiency increases as the population densities increase. As daily temperatures increase and water availability decreases, more and more animals will gather around the remaining available water sources. These areas become important areas for maximizing breeding efficiency. This temporary or seasonal increase in population density increases the chance for males to encounter estrous females. Thus, although breeding occurs year-round, increased breeding and foaling may occur during this period of time.

4.5 POPULATION CONTROLS

The authorized officer may consider a number of population control methods to achieve and maintain WH&B population size within AML.

4.5.1 Natural Population Controls

The rate at which WH&B herd sizes naturally increase or decrease is affected by a number of factors, including the nutritional value of the forage consumed, weather, disease, and predation. Experience gained in managing WH&B and other large herbivores indicates that soil, vegetation, and water resources are almost always severely damaged before these factors negatively affect population growth rates. Human intervention may be necessary when these factors, acting alone or in combination, do not exert sufficient influence to maintain WH&B population size within AML.

4.5.2 Gather and Removal

When the authorized officer has determined that excess WH&B exist, gathers to capture and remove the animals immediately or as soon as possible are required. For additional information, refer to BLM Manual Section 4720 (Removal) and 43 CFR 4720.1, 4740.1 and 2.

4.5.3 Reduce Population Growth Rates

During gather or herd management area planning, the authorized officer should consider a range of alternatives to reduce population growth rates and extend the gather cycle for all wild horse herds with annual growth rates greater than or equal to 5 percent. Alternatives may include but are not limited to: use of fertility control, adjustments in the sex ratio in favor of males, a combination of fertility control and sex ratio adjustment, and management of selected HMAs for non-reproducing wild horses. Additional management alternatives (tools) may be considered in the future, pending further research (see Chapter 8).

4.5.3.1 Use of Fertility Control as a Tool to Slow Population Growth Rates

a. Use of Porcine Zona Pellucida (PZP). There are two forms of the conventional PZP agent:

- The 1-year agent, delivered as a liquid primer injection and follow-up booster one month later; additional boosters must be injected annually by hand or by darting to continue treatment.

- The 22-month agent that includes the same primer shot as the one-year agent as well as a second injection of three time-release pellets (1-, 3- and 12-month pellets) to booster the vaccine over a 12-month period of time.

Foaling rates of 6 percent in Year One, 14 percent in Year Two and 32 percent in Year Three following treatment compared with 54 percent foaling in untreated controls have been reported for PZP-22 (Turner, 2007). Maximum effectiveness is not achieved unless mares are treated during a 3-4 month window prior to foaling. Research has shown that the best time to apply PZP is during the winter gather season (i.e., November-February).

The use of PZP, under an investigational exemption held by the Humane Society of the United States, requires treated mares to be physically marked (freeze branded) or readily identifiable in order to be compliant with FDA requirements. Application is limited to individuals specifically trained to handle, mix, and administer the product. Post-treatment monitoring in accordance with the Standard Operating Procedures (SOPs) is required.

As part of an appropriate environmental analysis, the authorized officer will analyze the use of the 22-month PZP vaccine in all wild horse herds, particularly those where: (1) the annual herd growth rate is greater than 5 percent and (2) the post-gather herd size is 50 animals or greater. Fertility control will be most effective when treatment of 50-90 percent of all breeding-age mares within the herd is possible using application in conjunction with gathers or remote delivery (darting). Our current understanding is that to maximize treatment effects, at least 90 percent of all mares should be treated.

The authorized officer should apply the 22-month PZP vaccine to all release mares when the NEPA analysis supports its use. In herds where sex ratio adjustments are made, fertility control may be implemented in combination with sex ratio adjustments to further reduce population growth rates.

b. Increased Use of PZP. One option to slow population growth rates (and reduce the number of excess wild horses removed) would be to gather selected HMAs and apply PZP-22 every 2 years. Because PZP does not totally eliminate reproduction, some excess horses may need to be removed from treated herds over time. Implementation should generally be limited to HMAs that have had high gather efficiencies (i.e., a high percentage of the actual population is captured). Because 70-90 percent of the breeding-age mares may need to be treated to effectively reduce population growth rates, 80-100 percent of the actual population may need to be captured.

c. Remote Application of PZP. Remote application of the 1-year formulation of PZP is problematic, as it is very difficult to approach most wild horses closely enough to allow darting (i.e., follow-up treatment). Remote application of PZP-22 is not possible at the present time since the pellets must be administered by hand injection.

   Remote application of the 1-year PZP agent may be considered for herds where individual horses can be identified (consistent with FDA requirements) and are approachable. Remote application is limited to individuals specifically trained to administer the product by darting.

4.5.3.2 Adjust Male/Female Sex Ratios

The authorized officer should consider alternatives which would manage WH&B herds for a sex ratio with a female component of less than or equal to 50 percent, as this reduces the population growth rate and extends the gather cycle. See Chapter 4 (4.4.1).

Adjusting sex ratios to favor males is another possible management tool which should be considered when the suppression of herd growth rate is desired. This management option should be considered in HMAs and complexes where the low end of AML is greater than 150 animals. Implementation of sex ratio adjustments is most feasible during maintenance gathers (4-5 years after AML is achieved). Sex ratio adjustments may be accomplished by shifting the overall sex ratio to favor males by (1) releasing greater numbers of stallions post-gather or (2) releasing geldings back to their home range following castration. Adjusting the sex ratio so that males comprise 60-70 percent of the adult herd could be considered.

Herd dynamics may change somewhat with adjustments in sex ratios. An increase in the proportion of stallions may have a greater impact when water resources are limited and bands are more concentrated.

Though additional information is needed, geldings are likely to have fewer impacts on the herd's social structure than would an increase in the proportion of stallions. Based on anecdotal observations, geldings released back to their home range: (1) tend to remain near where they were released (with adequate forage and water), (2) form small bachelor groups rather than join

with a reproducing band, (3) maintain better body condition than the herd average because they are sexually inactive, (4) live longer in comparison to sexually active horses, and (5) were easy to recapture (many have been recaptured and released several times).

Post-treatment monitoring should be conducted to observe behavior of individual animals and the herd during the first breeding season following treatment. Monitoring should be designed to determine whether bachelor stallions or geldings interfere with breeding harems, and whether there is increased competition for forage or water. Monitoring should also be designed to determine if the bachelor geldings form bands or intermix with the breeding population and whether band size changes with a greater proportion of stallions. This monitoring information will be used to determine if sex ratio adjustment is an effective population management technique that should be continued.

If post-treatment monitoring indicates that initial introductions of geldings or a greater proportion of stallions have resulted in negative impacts to breeding harems, mitigation could include removal of the additional stallions or geldings in whole or in part, no further introductions of stallions or geldings during future gathers, or release of a larger proportion of mares during the next gather. The need for post-treatment monitoring will decrease as the effectiveness of sex ratio adjustments as a tool to slow population growth rates is determined.

4.5.4 Manage Selected HMAs for Non-Reproducing Wild Horses

Under the WFRHBA (16 USC § 1333(b)(1)), the authorized officer may determine whether AML should be achieved by removal of excess animals, or if options such as sterilization or natural population controls should be implemented. Consistent with this authority, some selected HMAs may be managed for non-reproducing wild horses to aid in controlling on the range population numbers.

4.5.4.1 Manage HMAs for Non-Reproducing Wild Horses

LUPs should identify the HMAs to be managed for non-reproducing wild horses and the criteria for their selection. Completion of additional site-specific environmental analysis, issuance of a decision, and providing opportunity for administrative review under 43 CFR Part 4.21 may also be necessary.

Actual on-the-ground implementation would be influenced by gather efficiency and it may take several gathers to work toward an HMA with non-reproducing wild horses. Animals would be gathered to the extent possible and sterilized for return to the range, or removed. A safe, effective and humane means to sterilize stallions is castration, but a safe, effective and humane means to sterilize females has not yet been perfected. Therefore, initial efforts should focus on returning sterilized males to the HMA of origin. Sterilized males from HMAs with similar environments may be added as long as population size remains within AML. Care should be taken to ensure they are introduced and located near other animals in areas with good water and forage.

4.5.4.2 Manage Reproducing and Non-Reproducing Wild Horses in Selected HMAs

In selected HMAs with large AMLs, management of both reproducing and non-reproducing wild horses could be considered. As an example, non-reproducing wild horses could be geldings released back to their home range HMA following castration. Post-treatment monitoring and/or mitigation would be conducted as discussed in 4.5.3.2 above.

4.6 PRIORITIES FOR GATHER AND REMOVAL

When removal of excess WH&B from the range is necessary, gathers shall be prioritized in the following order:

- Emergencies
- Court Orders
- Nuisance animals (public health and safety)
- Impacts to threatened, endangered, or sensitive species (TES)
- WH&B located outside the HMA in areas not designated for their long-term maintenance
- Landowner request
- To achieve and maintain population size within AML
- Coordinate gathers across State, District and/ or Field Office boundaries and conduct gathers jointly whenever possible to improve gather efficiency and implementation of other population control measures such as application of fertility control and sex ratio adjustments.

4.7 NATIONAL GATHER SCHEDULE

A National Gather Schedule is developed annually based on the need to remove excess WH&B to achieve or maintain AML and the available funding and facility space. Situations that may require adjustments to the National Gather Schedule are: (1) Emergencies and (2) Escalating Problems.

4.7.1 Escalating Problems

Escalating problems are defined as conditions that deteriorate over time. The key indicator is a decline in the amount of forage or water available for WH&B use, which result in negative impacts to animal condition and rangeland health. Causal factors are normally drought or animal numbers in excess of AML. These situations can be detected in advance and are managed through the normal planning process. See BLM Manual Section 4720.21.

4.7.2 Emergencies

Emergencies generally are unexpected events that threaten the health and welfare of a WH&B population and/or their habitat. Examples of emergencies include fire, insect infestation, disease, or other events of a catastrophic and unanticipated nature. Immediate action is normally required. For some emergency actions, it may be appropriate to use alternative means or

procedures to comply with NEPA (see BLM NEPA Handbook, H-1790-1: National Environmental Policy Act Handbook, Chapter 2.3 Emergency Actions). If timeframes permit, a gather plan environmental assessment should be prepared prior to WH&B removal. If this is not possible, emergency actions should be documented and a report prepared after resolution of the problem. Public notification can be addressed through a press release. See BLM Manual Section 4720.22.

4.8 POPULATION MODELING

Version 3.2 of the Winn Equus population model developed by Dr. Steven Jenkins will be used during gather or herd management area planning to analyze and compare the effects of proposed wild horse management. The model is not designed for use on burros.

The model's primary purpose is to analyze and compare the effects of the proposed action (and alternatives) on population size, average population growth rate, and average removal number. Possible management alternatives or strategies may include, but are not limited to:

- Proposals to gather/remove excess animals, with or without fertility control.
- Proposals involving various gather cycles.
- Proposals to make adjustments in sex ratios.
- Proposals to manage all or a portion of a herd as a non-reproducing population.
- Proposals for gate-cut or selective removal gather.
- No Action.

Another objective of the modeling is to identify whether any of the alternatives would be likely to "crash" the population based on a number of stochastic factors (varying environmental conditions).

Use of the Win Equus population model requires the following:

- **Gather Planning:** Run the model for 10 years and 100 trials; select and display the most typical trial.
- **Herd Management Area Planning:** Run the model for 20 years and 100 trials; select and display the most typical trial.
- **Adjustment of Sex Ratios:** Select 100 percent gather for mares and adjust (decrease) the gather percentage for studs to achieve the desired post-gather sex ratio.
- **Results Analysis:** Drop the highest trial and the lowest trial and analyze and compare the remaining trials.

4.9 HUMANE DESTRUCTION

The BLM authorized officer will euthanize or authorize the euthanasia of a wild horse or burro when any of the following conditions exist:

1. Displays a hopeless prognosis for life.

2. Is affected by a chronic or incurable disease, injury, lameness or serious physical defect (includes severe tooth loss or wear, club feet, and other severe acquired or congenital abnormalities).

3. Would require continuous treatment for the relief of pain and suffering in a domestic setting.

4. Is incapable of maintaining a Henneke body condition score greater than or equal to 3, in its present environment.

5. Has an acute or chronic illness, injury, physical condition or lameness that would not allow the animal to live and interact with other horses, keep up with its peers or maintain an acceptable quality of life consistently or for the foreseeable future.

6. A State or Federal animal health official orders the humane destruction of the animal(s) as a disease control measure.

7. Exhibits dangerous characteristics beyond those inherently associated with the wild characteristics of wild horses and burros.

    a. Dangerous animals are defined as those horses or burros that are unusually aggressive and pose an unacceptable risk of injury to humans or other animals.

    b. Unusually dangerous horses or burros possess characteristics that are not desirable to breed into the wild herd.

    c. It is also reasonable to conclude that an average adopter could not humanely care for the animal.

CHAPTER 5—INVENTORY AND MONITORING

GENERAL

The authorized officer is required to identify, plan, collect and analyze the resource monitoring data necessary to prepare resource management plans, plan amendments, gather plans, herd management area plans or other associated environmental documents through which WH&B management decisions are made.

Inventory (monitoring) shall be completed in order to determine:

- If an overpopulation of WH&B exists and action is needed to remove the excess animals.
- WH&B AMLs; and,
- If AMLs should be achieved by removal of the excess animals or other appropriate means.

Monitoring data is needed to support AML establishment and decisions to remove excess WH&B. Various rulings from the Interior Board of Land Appeals (IBLA) underscore the need to base WH&B management decisions on the results of monitoring.

5.1 HABITAT MONITORING

The primary purpose of habitat monitoring is to collect the resource data necessary to:

- Make a determination of excess animals (i.e., support the need to gather and remove excess wild horses or burros).
- Establish or adjust AML.
- Develop or revise HMAPs.
- Evaluate conformance with Land Health Standards, LUP goals and objectives, or other site-specific or landscape-level objectives.

Collection of habitat monitoring data should be coordinated with other resource programs (e.g., range, watershed, wildlife) to maximize efficiency and minimize duplication.

Appendix 2 (Habitat Monitoring References) provides a list of BLM Technical References that can assist in planning for, and collection and evaluation of monitoring data. BLM Technical References can be found at: http://www.blm.gov/nstc/library/techref.htm

5.1.1 Annual Monitoring

Annual monitoring objectives include:

- Determine whether or not forage and water is adequate to support the animals in a healthy condition through the remainder of the year.
- Assess and evaluate animal condition.

To achieve these objectives, monitoring efforts should focus on the following:

- Evaluate current year's forage production and water flows.
- Evaluate/measure use, map patterns of use and monitor seasonal distribution/movement.
- Evaluate WH&B body condition.

Data collection to accomplish the above could include:

1. Photographs and Field Inspection Notes. Document observations on current year's growing conditions (average, below average or above average precipitation and soil moisture); plant phenology (are plants maturing earlier or later than normal); and forage production and water flows (average, below normal, above normal). When taking photographs, label each photograph with the date and the location to facilitate re-photographing the area in the future.

2. Use Mapping. Map utilization of current year's growth. Where possible, document forage utilization by WH&B in rest pastures or prior to livestock use. Where separation of use by type of animal is not possible, map total utilization at the end of the season. Use the information collected to identify and establish key areas, determine distribution, and seasonal use areas. If mapping utilization of the HMA on an annual basis isn't possible, focus monitoring on measuring utilization at key areas used by WH&B within the HMA on an annual and continuing basis.

3. Utilization. Estimate the proportion of annual forage production used by herbivores (WH&B, domestic livestock, wildlife, and insects).

4. Residual Vegetation or Stubble Height, Woody Species Use or Streambank Alteration. Measuring stubble height, use on woody species, and the degree of streambank utilization occurring annually (especially in rest pastures or prior to livestock use) may also be helpful in documenting resource impacts associated with WH&B use.

5. Grazing Use Records. Summarize the actual grazing use (animal unit months of forage) by livestock, WH&B, and wildlife by unit or pasture for the year.

6. Weather Data. Document information on temperature, precipitation, and growing conditions.

7. Animal Condition. Using the Henneke Body Condition Scoring (BCS) system, document the number of animals seen, where they were observed, and their BCS class. Document average group size (e.g., animals are concentrating in large groups or scattered, small groups, evidence of lameness, or other possible animal health concerns). This information may be used to assist in the evaluation of TNEB within the HMA.

When collected, data should be filed in the 4710-Herd Management case file and cross-referenced to the applicable rangeland management or other resource monitoring files.

5.1.2 Long-Term Monitoring

The objective of long-term monitoring is to determine whether management is resulting in significant progress toward attaining Land Health Standards, other applicable site-specific or landscape-level objectives, or changes in range ecological condition and trend (up, stable or downward). Data are typically collected by an interdisciplinary team of resource specialists in preparation for a formal and detailed evaluation of current management and its effect on resource conditions.

5.1.2.1 Ecological Sites

Rangeland landscapes are divided into ecological sites for the purposes of inventory, evaluation and management. Each site is defined and described by the Natural Resources Conservation Service (NRCS) based on climate, geology, soils, vegetation and other environmental factors. An ecological site is also described based on its ability to produce and support a characteristic plant community (i.e., kind, amount, and proportion of natural vegetation). Ecological site descriptions can be used to evaluate current management and to identify the potential effects in range ecological conditions or trends that could be expected from proposed changes in WH&B management. Ecological site descriptions for each Major Land Resource Area (MLRA) are available from NRCS. If an area has not yet been inventoried by NRCS, an interdisciplinary team of resource specialists will use the best available data to identify the ecological sites in the HMA.

5.1.2.2 Riparian Areas

Properly functioning riparian areas produce abundant forage, important habitats for fish and wildlife, and improve water quality and quantity. Functional-at-risk riparian areas have one or more attributes which place them at risk of deterioration, while nonfunctional riparian areas are unable to capture sediment, enhance infiltration, recharge aquifers or dissipate high energy flows. Assessments of proper functioning condition can be used to identify issues, establish objectives, and propose and evaluate changes in WH&B management.

5.1.2.3 Key Areas

Key areas are selected to monitor changes in range ecological condition or trend across representative areas within the HMA or complex which may result from current WH&B management. Key areas may be selected to represent a particular plant community or a specific ecological site. They should also be selected to represent ecological conditions and trends, utilization or use patterns, seasonal distribution, and resource production within the HMA or complex.

Long-term monitoring within key areas may include measurements of frequency, production, and cover (canopy cover, foliar cover, ground cover and basal cover). Plots are generally read at intervals of 5-10 to 15-20 years.

5.1.2.4 Key Species

Key plant species are selected for forage utilization studies. Key species are important forage species within plant communities that can indicate changes in resource conditions resulting from WH&B management. More than one key species may be selected, depending on management objectives.

Key forage species are used to indicate the allowable degree of forage utilization on a key area which promotes attainment of attaining vegetation management objectives. They may be identified during land use planning, or result from habitat management objectives established during site-specific planning efforts such as herd management area planning.

5.1.3 Integrated (Interdisciplinary) Resource Monitoring Plans

Development of integrated (interdisciplinary) resource monitoring plans can help assure that the data needed to support WH&B management decisions is collected in an effective and efficient manner. Resource monitoring plans should identify the following:

- **Who** (The resource specialty responsible for data collection, i.e., WH&B specialist, range specialist, etc.).
- **What** (Data to be collected).
- **When** (Time of year data should be collected and how often).
- **Where** (Location(s) for data collection, i.e., location and documentation of key areas).
- **Why (**The specific monitoring objective).
- **How** (Methods to be used).

Also refer to Appendix 4 (Table 4.2).

5.2 POPULATION MONITORING

An accurate and current assessment of WH&B health and condition, as well as population size, growth rate, and distribution, is needed for proper WH&B management. At a minimum, population surveys should be conducted every 2 years whenever possible, and within 6-12 months prior to establishing the need to gather and remove excess WH&B.

5.2.1 Population Estimation

WH&B population size should be estimated primarily by aerial survey. See BLM Manual Section 4710.45.

1. Aerial surveys will be conducted and documented using standardized sampling methods and procedures. Survey methods (types of aircraft and techniques) should utilize the most effective and cost-efficient techniques for the specific HMA or complex.

2. To permit comparison with prior data and detect population trends, aerial surveys should be conducted during the same time of the year, using the same or similar type of equipment, methodology, and personnel.

3. The following data should be should be recorded during aerial surveys:

   - HMA name and number
   - State/District or Field Office
   - Survey date
   - Observer(s) name
   - Weather conditions
   - Type of aircraft used
   - Altitude
   - Flight time
   - Time of day
   - Survey method (direct count, simultaneous double-count, mark-resight, etc.)
   - Flight path, number and location of animals seen in GPS/GIS data format
   - Number of adults, number of foals
   - Basic herd health and condition information
   - Basic information about range, forage or water conditions, wildlife, or livestock use, etc.

4. In areas where gather efficiencies have been historically low or WH&B range widely, a post-gather survey should be conducted in the 6-12 months following gather completion to obtain a more accurate estimate of the number of WH&B left on the range.

5. Monitoring WH&B distribution is critical in identifying seasonal use areas, determining movement patterns and identifying areas for habitat monitoring. While seasonal distribution may vary over the years, movement is normally related to the abundance and quality of the forage, climate, weather patterns, and availability of water.

6. The HMA monitoring file shall contain a permanent record of data collected during the aerial surveys and the results should be entered into the Wild Horse and Burro Program System (WHBPS) and the local GIS data base.

5.2.2 Herd Condition and Health Monitoring During Gathers

The condition class of individual horses should be evaluated and documented during gathers using the Henneke Body Condition Scoring System (refer to H-4760-1: Compliance Handbook).

1. Data should also be collected on age structure and sex ratio. This information can be used to evaluate the effects of the management actions on herd health and condition.

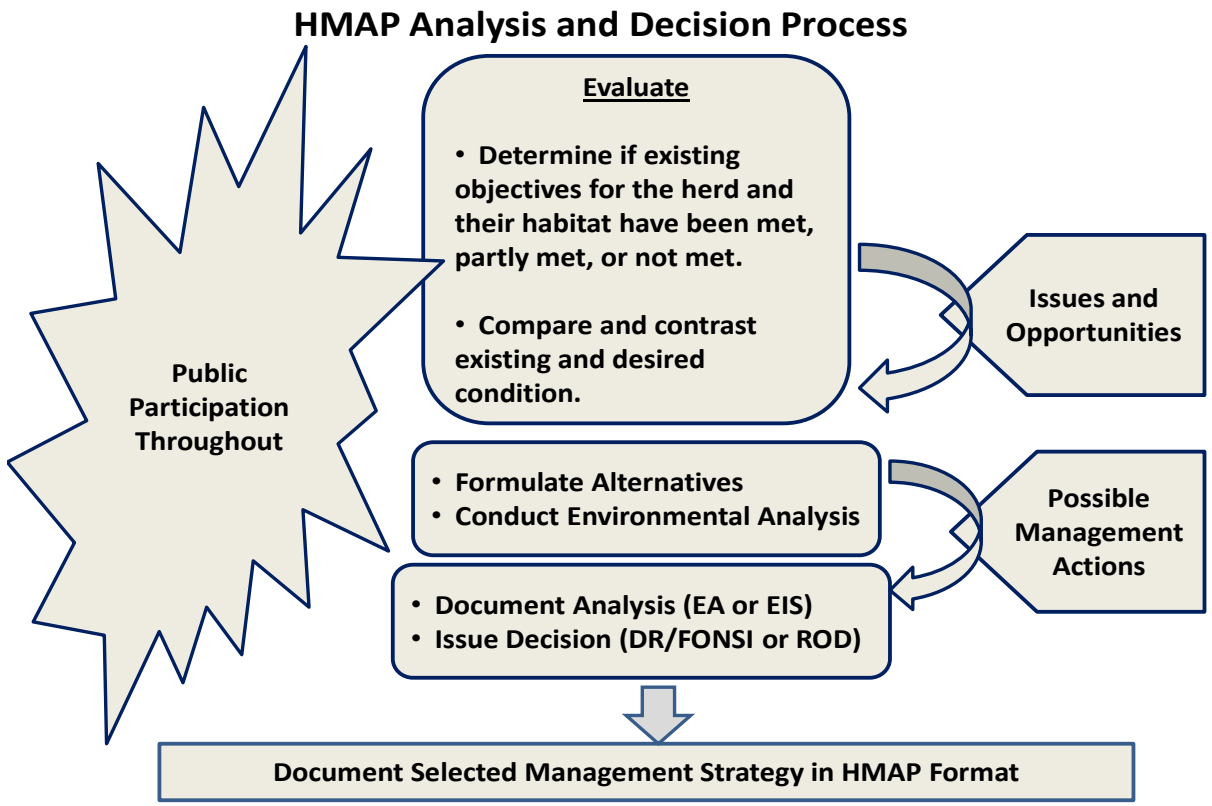
2. Estimate the number of WH&B left on the range (number remaining ungathered) following each gather.

3. Other data that may be collected during gather operations include: parasite load, disease (from blood samples), percentage of pregnant mares (through analysis of blood or fecal samples), and/or the effects of fertility control.

4. The incidence of albinism, parrot mouth, club feet, severely crooked legs or other physical deformities should also be documented and the subject animals removed from the population when possible. The incidence of these traits should be minimized within individual herds over time.

CHAPTER 6—HERD MANAGEMENT AREA PLANNING

GENERAL



Herd Management Area Plans (HMAPs) identify and set objectives for WH&B herds and their habitat. HMAPs are prepared with public involvement through a site-specific environmental analysis and decision process (NEPA). During the NEPA process, the environmental impacts associated with a range of alternative management strategies for the WH&B herd and its habitat is analyzed.

The approved HMAP outlines the selected management actions, together with the management and monitoring objectives which, when implemented, would make progress toward achieving land health standards, LUP goals/objectives, and other relevant objectives.

6.1 HMAP ANALYSIS AND DECISION PROCESS

An overview of the HMAP analysis process is provided in Figure 6.1. Also refer to Appendix 4 (Herd Management Area Planning) for additional information.

Figure 6.1
Overview of the HMAP Analysis and Decision Process

6.1.1 Evaluate Current Management

The first step in the HMAP analysis process should generally be to evaluate existing management. At the conclusion of the management evaluation, a report will be prepared and made available to the public for a 30-day review and comment period (public scoping). To facilitate public review, the document will be posted on the state, district or field office web page.[1] The management evaluation report is not a decision subject to administrative appeal.[2] Rather, the report documents the key issues identified as a result of the management evaluation. A range of the possible management alternatives (Proposed Action and Alternatives) that would address or resolve the identified issues may also be identified. The range of alternative may be expanded as a result of scoping comments.

Key steps in the management evaluation process include:

1. Review existing goals and objectives for the herd and its habitat and determine whether these have been met, partly met, or not met. Incorporate a summary of the rationale supporting BLM's determination in the evaluation report.

2. Compare and contrast the existing and desired condition for the herd and its habitat. Refer to the information in Chapter 3 (Habitat Management) and Chapter 4 (Population Management) as a starting point for the analysis.

3. Document the gaps (or differences) between the current and desired conditions. These differences represent the issues to be addressed and resolved (i.e., the purpose and need for action).

4. Identify the possible management actions that could be implemented in response to the identified issues.

5. Formulate a range of alternative management strategies for the herd and its habitat from the list of possible management actions (Proposed Action and Alternatives). Each alternative considered should meet the purpose and need for action and respond to the identified issues in whole or in part.

6. Finalize the management evaluation report and provide it to the public for a 30-day review and comment period (i.e., public scoping).

6.1.2 Conduct and Document the Site-Specific Environmental Analysis

As a next step, conduct and document the interdisciplinary, site-specific analysis of potential impacts that could result from implementation of the No Action (generally defined as "Continue

[1] If an Environmental Impact Statement (EIS) is prepared, scoping will be conducted following issuance of a Federal Register Notice.

[2] Once the HMAP decision is made, the Evaluation Report is part of the administrative record for that decision.

Existing Management" for HMAP development and analysis), the Proposed Action, and other action alternatives. Refer to H-1790-1: National Environmental Policy Act Handbook.

Though it may be appropriate in some instances to prepare an Environmental Impact Statement (EIS), normally an environmental assessment (EA) is prepared to document and analyze an HMAP decision. The section below provides guidance about how an HMAP EA may be structured.

6.1.2.1 Preparing the HMAP Environmental Assessment (EA)

1. Introduction. Limit the information included in the "Introduction" section of the EA to the minimum needed to allow the reader to understand the existing situation. Include a brief description of the HMA and its location, and the AML (and when/how it was established). Describe the purpose and need for the Proposed HMAP. Identify the relevant issues, summarize the results of public scoping, and document how the BLM used the comments in preparing the preliminary environmental assessment. Tier the analysis to applicable decisions in the LUP.

2. Proposed Action and Alternatives. Each alternative considered in detail in the EA shall meet the purpose and need for action and respond to the identified issues to varying degrees. The range of alternatives considered will include a No Action Alternative (i.e., Continue Existing Management) and the Proposed Action (Proposed HMAP). Other alternatives should be developed in response to the purpose and need and the identified issues, as appropriate.

   Each alternative will describe the strategy to be used to manage the herd and its habitat over the long-term, together with the associated management, monitoring and implementation objectives. In formulating the alternative management strategies, various management tools may be considered to protect, control and manage WH&B populations and their habitat. For example, consider differing gather seasons or methods, various tools to slow population growth, or various habitat improvement tools, projects or techniques.

3. Management Objectives and Actions. Management objectives and actions may differ by alternative. This section of the EA would summarize the objectives and actions specific to each alternative.

   For each alternative specify: (a) the proposed habitat and population management objectives, (b) the associated management actions (e.g. implementation objectives), and (c) the proposed monitoring objectives. These objectives and actions should conform to and be consistent with LUP goals.

   a. SMART Objectives. Well-written objectives should be specific, measurable, achievable/attainable, reasonable/relevant and trackable within a specified timeframe (SMART):

1) Specific: Specifies what and where.
2) Measurable: Identifies the amount of change expected; desired change can be measured or observed.
3) Achievable/Attainable: Realistic for the specific site conditions.
4) Reasonable/Relevant: Limited in scope, within the BLM's control and influence, measures results (not activities).
5) Trackable/Timeframe: Identifies where the activity will occur, short- and long-range targets, as well as interim steps and a plan to monitor progress.

b. Habitat Objectives. Habitat objectives may involve vegetation, trend or key area objectives for upland vegetation or riparian plant communities within the HMA or complex or objectives to maintain or improve the wild, free-roaming behavior of the population. Site-specific objectives to improve habitat conditions (e.g., forage or water) may also be established.

Examples of SMART Objective(s)

- ❒ Improve riparian condition from functioning at-risk (FAR) in 1998 to properly functioning condition (PFC) by decreasing utilization from heavy to moderate within a ½ mile circumference of Bird Spring.
- ❒ Adjust sex ratios from 40 percent studs and 60 percent mares in 2010 to 60 percent studs and 40 percent mares by 2014.

c. Population Objectives. These objectives would establish a framework for management of the WH&B herd over the longer term. Objectives could include when and how AML would be adjusted in the future, or when and how the population within the HMA would be gathered. Among other population management parameters, objectives may be identified for desired age structure and sex ratio, animal condition, phenotype, genetic diversity, population growth rate, or selective removal criteria. These objectives may be based on historical attributes or other management considerations.

d. Monitoring Objectives. As necessary, identify a monitoring objective that would measure the progress made toward achieving proposed habitat or population management objectives.

e. Implementation Objectives (Management Actions). Implementation objectives are management actions that, when implemented, are expected to make progress toward attaining the proposed habitat or population management objectives. These could include application of fertility control, adjustment of sex ratios to favor males, or other actions to slow population growth, management actions to assure genetic diversity or achieve the desired sex ratio or age structure for the WH&B herd, or range improvement projects.

4. Description of the Affected Environment and Environmental Impacts

   a. General Description of the Affected Environment. This section of the EA should include a concise general description of the HMA or HMA complex. Voluminous material may be included in the EA appendix. Maps, tables, charts or graphs may also be useful in summarizing or displaying relevant information. Information could include:

      1) General information about the HMA or complex's size, location, acres of public land or other land ownership, general description of topography, elevation, climate, and dominant vegetation.

      2) A summary of the WH&B herd's history using best available data. This could include the probable origin of the WH&B population, identification of the general type of WH&B historically occupying the HMA, any interchange between this herd and adjacent HMAs, known genetic diversity (observed heterozygosity or Ho) and any introductions of WH&B from another HMA.

      3) A brief discussion of any historic adjustments that have been made in the HA/HMA boundary, and the name and date of the decision document(s) used to initiate those adjustments. Maps or descriptions of HA/HMA boundaries may also be included.

      4) Initial forage allocations together with the existing AML range. The name and date of any decision document(s) used to establish or adjust AML along with a brief description of the causal factors leading to the change.

      5) Any population and habitat management actions or events that have impacted herd size including scheduled, emergency or nuisance animal gathers, application of fertility control, and the occurrence of catastrophic events such as extended drought or wildfire.

      6) A concise list of applicable LUP decisions that affect the HA/HMA, including any constraints on WH&B distribution and management (voluminous information can be included in an appendix to the EA).

      7) A list of applicable Land Health Standards (these may be included in an appendix to the EA or an internet address can be provided if they are available on the internet).

      8) Brief descriptions of other resource values and uses relative to the management of WH&B, as appropriate. This could include: authorized and/or actual livestock use, TES species and their habitat, Wilderness, Wilderness Study Areas (WSAs), etc.

b. Description of the Affected Environment and Environmental Impacts. For each element of the human environment that has the potential to be affected by the Proposed Action or alternatives, describe the existing situation (affected environment). Also describe the direct and indirect impacts to these resources that could result from implementation of the Proposed Action and Alternatives.

5. Cumulative Impacts. The National Environmental Policy Act (NEPA) regulations define cumulative impacts as impacts on the environment that result from the incremental impact of the Proposed Action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such actions (40 CFR 1508.7). Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

   In assessing the cumulative impacts associated with preparation of a proposed HMAP, first define the area of potential effect—cumulative impacts will be evaluated within the area of potential effect.

   Next define the issues and resource values identified during scoping that are of major importance (in accordance with the 1994 BLM *Guidelines for Assessing and Documenting Cumulative Impacts*, the cumulative impacts analysis should be focused on only those issues and resource values identified during scoping that are of major importance).

6. Public Review and Comment. The HMAP environmental assessment shall be made available to the public for a 30-day review and comment period by posting on the state/district or field office web page. See H-1790-1 for instructions if an EIS has been prepared.

7. Finalize the HMAP EA. Soliciting public comments obligates reviewers to give fair consideration to the input received. Summarize the results of public review and comment and document how the BLM used the comments in finalizing the environmental assessment.

6.1.2.2 Prepare the Decision Record and Finding of No Significant Impact (FONSI) or an EIS and Record of Decision (ROD)

Based on the analysis of potential environmental consequences, the authorized officer will determine whether to prepare an EIS or issue a Decision Record (DR) and "Finding of No Significant Impact" (FONSI). A FONSI documents why implementation of the selected alternative will not result in environmental impacts that significantly affect the quality of the human environment. The DR identifies the authorized officer's final decision and is a separate and subsequent document to the FONSI. See H-1790-1 for additional information.

If an EIS has been prepared, due to the potential for significant environmental impacts, the authorized officer's final decision will be documented in a Record of Decision (ROD).

6.1.2.3 Prepare the HMAP

As a final step and to facilitate on-the-ground implementation, document the selected management strategy, together with the habitat and population management, monitoring and implementation objectives in HMAP format. The HMAP shall be included as an attachment to the authorized officer's final decision.

The approved HMAP should include the following components:

- **Introduction.** Briefly introduce or summarize the relevant background information (repetition of detailed information incorporated in the NEPA document is not required in the approved HMAP).

- **Management Strategy.** Summarize the selected management strategy as outlined in the EA together with the site-specific habitat and population objectives and management actions established to accomplish the objectives.

- **Monitoring and Evaluation Plan** (refer to 6.1.2.3.1).

- **Tracking Log/Project Implementation Schedule** (refer to 6.1.2.3.2).

6.1.2.3.1 Resource Monitoring Plan/Schedule

The HMAP shall include a resource monitoring plan and schedule that will be used to facilitate the timely and effective completion of habitat and population monitoring. The plan should identify the specific monitoring item, the methodology to be used, the resource specialty needed to complete the monitoring (e.g., field office WH&B specialist, rangeland management specialist, wildlife biologist, etc.), where and when monitoring should occur, as well as any actions to be taken to adjust or adapt management as needed and appropriate pending monitoring results. The plan should include both habitat and population monitoring components. See Appendix 4 (Table 4.2).

6.1.2.3.2 Tracking Log/Project Implementation Schedule

The HMAP will include a tracking log and project implementation schedule to facilitate and monitor plan implementation. The tracking log may be developed in a tabular format, and will list the selected habitat and population management actions (what), the entity responsible for implementation (e.g. who -- BLM, USFS, volunteer groups, etc), and define where, when, and how often the action is to be completed. Columns to document the date the action was completed and/or implemented and for any remarks (e.g. project numbers from BLM's Rangeland Improvement Project system, etc) should also be included. See Appendix 4 (Table 4.3).

6.2 HMAP MONITORING AND EVALUATION

Resource (habitat and population) monitoring data should be analyzed periodically to determine whether minor adjustments in management are needed (adaptive management). Periodic evaluations are conducted to assure HMAP implementation is on track and to gauge progress toward achieving the selected habitat and population management and other relevant objectives. Refer to the process outlined in 6.1.1.

The goals for HMAP monitoring and evaluation are twofold: (1) to track implementation of the management actions/decisions outlined in the HMAP (implementation monitoring); and (2) to collect the data/information necessary to evaluate the effectiveness of those decisions (effectiveness monitoring).

1. Implementation Monitoring. Implementation monitoring tracks implementation of the selected management actions. It answers the question "Did we do it?" To assure selected management actions are being implemented in a timely manner, annual review is recommended.

2. Effectiveness Monitoring/HMAP Evaluation. Plan evaluation is the process of periodically reviewing the HMAP to determine if it is effective in making progress toward or accomplishing the approved habitat and population management objectives (plan evaluation typically occurs at intervals of 5, 10 or 15-20 years). Effectiveness monitoring answers the question "Did it work?"

   The HMAP shall also be evaluated to determine: (1) whether management goals and objectives are still appropriate or need to be revised, and (2) whether progress is being made toward achieving the goals and objectives, or additional management actions are needed (adaptive management). Evaluation of the HMAP could also be completed in conjunction with land health assessment.

   Evaluations that highlight the need for substantial changes may require consultation with interested public as well as appropriate NEPA analysis and documentation prior to implementation.

6.3 4710 CASE FILE

A 4710-Herd Management Area file shall be established for individual HMAs or complexes. The case file should include (but is not limited to) the following:

- A copy of the HMAP.
- HMA and HA maps.
- The associated NEPA and BLM decision documents (or a cross-reference to those documents).
- Any correspondence pertaining to HMA management.
- Aerial survey results.

- Field inspection reports and monitoring data (or a cross-reference to the applicable rangeland management or other case files).
- Information on habitat improvement projects (or a cross-reference to the applicable rangeland management or other case files).
- Final gather reports.
- Fertility control reports, if applicable.
- Results from periodic HMAP evaluations.

Additional 4710 case files may be created if the number and type of monitoring studies is large and varied (e.g. 4710-1, 4710-2, etc).

Relevant data and information should also be entered in a timely manner into WHBPS, as appropriate.

HA/HMA maps and a record of the HA/HMA history should be included in the 4710 HMA file. However, the HA and HMA boundaries delineated in the State GIS data base and provided to the National Coordinator for upload into the National Data Set serve as the official record. Any future changes to HA or HMA boundaries should be documented in the State GIS data base as well as in the HMAP file.

CHAPTER 7—DECISIONS AND APPEALS

7.1 DECISIONS

Implementation decisions form the basis for approval of on-the-ground management actions. When implemented, these actions further the incremental progress toward achieving LUP goals and objectives, Standards for Land Health, or other site-specific habitat or population management objectives. If proposed management is not in conformance with the LUP, the proposal shall be modified or rejected, or the LUP shall be amended or revised.

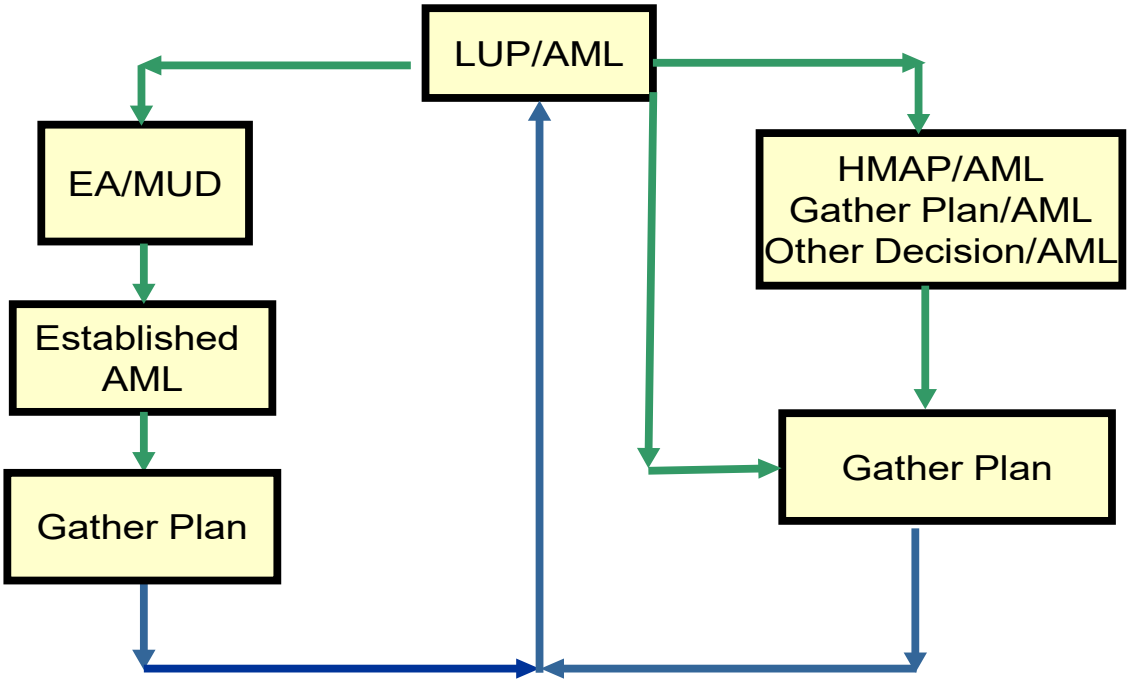
WH&B implementation decisions can include:

- Establishing or adjusting AML
- Developing HMAPs
- Population management actions
- Habitat improvement projects

Program-specific procedures must be followed when issuing a decision. WH&B implementation decisions can be made in a variety of ways and administrative review (appeal) requirements may vary based on the decisions made (Figure 7.1).

Figure 7.1
Decisions and Appeals Process

An Overview



Authority	43 CFR 4770.3(c)	43 CFR Part 4.21
Decision Type	Decisions to Gather/Remove Excess WH&B	AML, HMAP or Project Decisions
Effective Date	• *Emergency Removal Decisions:* make effective upon issuance. • *TNEB Removal Decisions:* make effective on a date specified in the decision *(*e.g., 31-76 days prior to proposed gather start).	Effective the day after the appeal period expires (i.e., 31 days) unless a petition for stay is filed.
Administrative Review Timeframe	Appeals and petitions for stay must be filed within 30 days of the date of the decision.	
Implementation Timeframe	Unless a petition for stay is granted, the gather and removal may proceed as outlined in the authorized officer's decision.	The authorized officer's decision may be implemented immediately if the Appeals Board either denies the petition for stay or fails to act on it within 45 calendar days of the expiration of the time for filing a notice of appeal.

* AML decisions issued as MUDs are heard by a OHA/ALJ and are not implementable until OHA has ruled.

7.1.1 AML Decisions

AML decisions determine the maximum number of WH&B to be managed in the HMA that results in a TNEB and avoids a deterioration of the range. Decisions to establish or adjust AML or establish a population range if the AML was initially set as a single number, can be made in a number of ways (refer to Figure 7.2).

Figure 7.2
AML Decisions

AML decisions are generally implementation decisions as compared to LUP decisions. All AML decisions must meet the following criteria:

1. AML is set based on in-depth analysis of site-specific resource monitoring data including grazing utilization, trend in range condition, actual use and climatic factors (i.e., AML is not set based on administrative convenience or single surveys); and

2. Guidelines and criteria for adjusting herd size are included. Refer to *Dahl v. Clark*, 600 F. Supp. 585 (D. Nev. 1984); *Animal Protection Institute*, 117 IBLA, 208, 219 (1990); and *Animal Protection Institute*, 109 IBLA 112, 118 (1989).

AML decisions may also be made through:

- Issuance of WH&B (single-use) decisions.

- Issuance of multiple-use decisions (MUDs, which allocate forage for domestic livestock, wildlife and WH&B).
- As a part of HMAP decisions.
- As part of gather/removal plan decisions.

AML is not generally established or adjusted as part of the gather planning (NEPA) process due to the in-depth and complex nature of the analysis required. Complexity also increases if allocation of the available forage for use by wildlife, livestock and WH&B will be made concurrently (e.g., MUDs).

If the authorized officer elects to formally review AML as part of the same environmental document which evaluates the proposed removal, the AML decision should be separated from the gather/removal decision. This may be accomplished by issuing separate Decision Records:

1. Gather/removal decision.
2. AML decision.

Separation of the two decisions is desirable because there are different rules governing the timing and appeals process for those decisions:

- Under 43 CFR 4770.3(c), the authorized officer can make decisions to remove wild horses or burros from public or private lands effective upon issuance or on a date specified in the decision, where removal is needed to preserve or maintain a thriving ecological balance and maintain a multiple use relationship.

- The authorized officer does not have similar authority with respect to issuing AML decisions, which, if no petition for stay is filed, become effective on the day after the expiration of the appeals period. See 43 CFR § 4.21(a)(2).

7.1.2 Gather/Removal Decisions

Prior to removing WH&B from public lands, the authorized officer must make a determination, based on current information, that excess animals are present and their removal is necessary to restore a TNEB and multiple-use relationship. BLM's authority to remove excess animals from public lands is found in 16 USC § 1333(b)(2) of the WFRHBA (as amended). This provision requires the BLM to immediately remove the animals upon determination that excess WH&B exist, so as to achieve appropriate management levels, restore a thriving natural ecological balance, and protect the range from the deterioration associated with the overpopulation.

In making the determination that excess WH&B are present and require immediate removal, the authorized officer will analyze current information including grazing utilization and distribution, trend in range ecological condition, actual use, climate (weather) data, current population inventory, WH&B located outside the HMA in areas not designated for their long-term maintenance and other factors which demonstrate removal is needed to restore or maintain the range. Justifying a removal based on nothing more than the established AML is not acceptable.

7.1.2.1 Environmental Analysis (Gather Plans)

The following tools can be used to focus the discussion during the site-specific environmental analysis conducted for Gather Plans:

1. Limit the analysis to that needed to determine the potential impacts associated with the Proposed Action and Alternatives, including No Action. Refer to H-1790-1 for a detailed discussion of the appropriate components of a NEPA analysis.

2. Tier the analysis to LUPs, HMAPs, or other relevant decision documents, as appropriate.

3. Incorporate previous analysis or decisions by reference (e.g., reference to previous AML decisions, HA/HMA boundary decisions, etc), as appropriate.

These tools allow reference to the information without the need to either include the documents in whole or in part, or to restate the information in voluminous detail.

7.1.2.2 Decision Record (Gather Plan)

Unless an emergency situation exists, gather/removal decisions shall be issued 31-76 days prior to the proposed gather start to provide an opportunity for administrative review of the authorized officer's decision to be completed. The Decision Record (DR) for Gather Plans that are documented in an environmental assessment should:

1. Summarize the substantive comments received and describe how BLM used these comments to finalize the environmental assessment. See 7.2 for additional information.

2. In accordance with 43 CFR 4770.3(c):

   - The authorized officer will issue gather decisions effective upon a date established in the decision in situations where removal is required by applicable law, or is necessary to preserve or maintain a thriving natural ecological balance and multiple use relationship.

   - When an emergency situation exists, and timeframes permit, a Gather Plan EA should be prepared and the decision should be made effective upon issuance. See BLM Manual Section 4720.36.

3. Cite the regulatory authority upon which the decision is based.

4. Explain the timeframe and procedures for filing an appeal.

5. Describe the procedures for requesting a stay of the action under 43 CFR 4.21.

7.1.3 Other Management Decisions

Other management decisions may include:

- Approval of HMAPs that establish site-specific population or habitat objectives or actions.
- Project-specific decisions (i.e., water development construction or reconstruction, etc.).

These decisions are made following site-specific environmental analysis (NEPA) with public involvement and are subject to administrative review (appeal) under 43 CFR 4.21.

7.1.4 Actions Excluded from Further NEPA Documentation

Certain actions may be categorically excluded from NEPA analysis (refer to H-1790-1, Chapter 4, Categorical Exclusions). Other actions may have already been adequately analyzed through NEPA and a Determination of NEPA Adequacy (DNA) may be prepared.

Before conducting a new NEPA analysis for a proposed Gather Plan, existing NEPA documentation should be reviewed to determine if it is adequate (i.e., review previous Gather Plan EAs together with the associated Decision Records and Findings of No Significant Impact). Changes in numbers of WH&B since the previous gather that result in changes in forage utilization, use patterns, and/or ecological conditions and trends, or changing environmental conditions such as drought, wildfire, noxious weed infestations, and others, may require that a new NEPA analysis be conducted.

If the existing NEPA documentation appears to be adequate, consult with the Office of the Solicitor to determine whether the issuance of a DNA may be appropriate.

7.2 PUBLIC INVOLVEMENT

The authorized officer may conduct public scoping. See H-1790-1, Chapter 6.3.

The authorized officer will provide the public 30 days to review and comment on the NEPA document, typically an Environmental Assessment that documents and analyzes the environmental effects of the BLM's Proposed Action.

The authorized officer shall make Gather Plan EAs and DNAs available to interested individuals, groups, and agencies for a 30-day review and comment period, except when an emergency situation exists. The NEPA document(s) identified in the DNA (e.g., the EA and Finding of No Significant Impact (FONSI)) will also be made available to the public for information.

The authorized officer should consider substantive comments and summarize how they were addressed in the NEPA document or DNA for the Gather Plan. This summary should be presented in the NEPA document, the DNA, or the decision document. See H-1790-1, Chapter 6.9 for additional information.

Possible options for responding to substantive comments include:

- Modifying one or more of the alternatives.
- Developing and evaluating additional alternatives.
- Supplementing, improving, or modifying the analysis.
- Making factual corrections.
- Explaining why the comments do not warrant further agency response, citing cases, authorities or reasons to support the BLM's position.

When an EIS has been prepared, follow the guidance provided in H-1790-1, Chapter 9.

7.3 APPEALS (ADMINISTRATIVE REVIEW)

Any party who is adversely affected by a final decision of the authorized officer may file an appeal and request a stay of the action. WH&B decisions are subject to administrative review (appeal) and remedies under the provisions of 43 CFR 4.21, 4.410, and 4770.3.

As a general matter, WH&B decisions will not become effective during the time in which a person adversely affected may file a notice of appeal. Unless a petition for a stay pending appeal is filed together with a timely notice of appeal, these decisions will become effective on the day after the expiration of the time during which a person adversely affected may file a notice of appeal (generally 31 days from the decision date). If a petition for stay pending appeal is filed together with a timely notice of appeal, a decision will become effective immediately if:

- The stay request is denied; or,
- The Interior Board of Land Appeals fails to act on the petition for a stay within 45 days from the date of the decision.

Under certain circumstances, however, the authorized officer may make decisions to gather/remove excess wild horses or burros effective upon issuance or on a date specified in the decision. See 43 CFR 4770.3(c).

Under the authority provided in 43 CFR 4770.3 (c), the authorized officer may make decisions to gather/remove excess wild horses or burros effective upon issuance or on a date specified in the decision.

When issued under this authority, the gather may be implemented unless a stay is granted or a Federal Court enjoins the gather.

7.3.1 AML Decisions

AML decisions are subject to administrative review:

1. When administrative review of multiple-use decisions (MUD) is requested, BLM may ask to combine the wild horse decision with the grazing decision for review by an administrative law judge (ALJ) in the Office of Hearings and Appeals (OHA).

2. Wild horse decisions are subject to administrative review by the Interior Board of Land Appeals (IBLA) in accordance with 43 CFR 4.21 and 4.410.

7.3.2 Gather/Removal Decisions

The authorized officer has the authority to make decisions to gather and remove excess WH&B effective upon issuance or on a date specified in the decision when removal is court ordered or is needed to preserve a thriving natural ecological balance and multiple use relationship.

Any party who is adversely affected by the authorized officer's final decision may file an appeal and/or request a stay of the action with the Interior Board of Land Appeals (IBLA). The appeal and/or request for stay must be filed within 30 days from the date of the decision and in accordance with the regulations found at 43 CFR 4.411(a).

7.3.3 HMAP or Other Management Decisions

AML, HMAP, or other management decisions are subject to administrative review through the IBLA under provisions of 43 CFR 4.21 and 4.410. Under this authority, decisions **cannot** be implemented effective upon issuance or on a date specified in the decision.

A notice of appeal must be filed in the office of the authorized officer within 30 days from the date of the decision. See 43 CFR 4.411.

CHAPTER 8—RESEARCH

GENERAL

Direction to conduct research is contained in the WFRHBA, 16 U.S.C. § 1333(b)(2)(C)(3), and the Strategic Plan for Management of Wild Horses and Burros on Public Lands (1992). In late 2000, the Midcontinent Ecological Science Center of the U. S. Geological Survey (USGS) was charged with developing a strategic research plan for the management of WH&B. The purpose of the strategic planning process was to:

- Review past progress and identify problems that could be addressed with research.
- Set broad research goals central to the BLM's mission for WH&B management.
- Establish specific, time-bound, measurable research goals, and strategies to achieve them.
- Evaluate the progress towards those goals at set time periods, and to readjust the planning as needed.

There had been no previous prioritization of the BLM's WH&B research and management needs, and no effort to develop a strategy for fulfilling those needs within a specified time period. The strategic planning process was designed to fill this void.

8.1 STRATEGIC RESEARCH PLAN

The Strategic Research Plan for Wild Horse and Burro Management identified research priorities to include health and handling, fertility control, population estimation and modeling, genetic conservation, habitat assessment and setting population goals. The components of fertility control and population estimation have been implemented and research is being conducted. Genetic diversity of WH&B herds is being evaluated. Other research projects may be initiated as needed to support the management of WH&B. Research results will be used to improve management practices within the WH&B program.

8.1.1 Development

The Strategic Research Plan was a joint effort between the USGS, the BLM, the Animal and Plant Health Inspection Service (APHIS), and the U.S. Department of Agriculture (USDA). The plan was developed over a period of 2 years with input from 39 subject area experts representing 11 universities, 3 Federal agencies (BLM, USGS, APHIS), and two State wildlife agencies.

The USGS took the lead role in planning and coordinating meetings of the expert committees and in drafting the Strategic Plan based on committee and agency input. Assisting in this effort were the BLM's National WH&B Research Coordinator and equine health experts from APHIS.

Principal input from the USGS was focused on topics of contraception, aerial population estimation, population modeling, and genetics. Principal input from APHIS was focused on topics of disease and animal health monitoring and surveillance.

Advice and input has also come from BLM including managers and specialists assigned to the WH&B program, the National WH&B Advisory Board, and WH&B staff in the Washington Office. Advice and input was also provided by the BLM Director's Science Advisory Committee, and from seven topic-specific advisory panels that were convened by the USGS.

8.2 RESEARCH REQUESTS

A National Research Advisory Team exists to review research proposals, monitor research project progress, update the Strategy as necessary, and provide recommendations to the WH&B Division Chief. The Research Advisory Team has been formed with equal participation by the BLM (BLM's National WH&B Research Coordinator), the USGS, and APHIS.

All requests for research and/or research proposals pertaining to the Wild Horse and Burro program, whether generated from the field or through field-related contacts, are to be directed to the Research Advisory Team for review. This Team is also available to assist field offices with the development of research proposals. Proposal format and submission should be coordinated through the National WH&B Research Coordinator. Proposals will be reviewed on an as-needed basis and recommendations for funding will be made directly to the WH&B Division Chief.

8.3 RESEARCH PROJECTS

8.3.1 Fertility Control

An effective, safe, and cost-effective fertility control agent is an essential tool in the management of wild horses. A Fertility Control Field Trial Plan has been developed and field research is underway for two components of the Plan: (1) Individual-Based Trials and (2) Population-Based Trials. Over the last decade, BLM research efforts in fertility control have been focused on PZP (Porcine zona pellucida) and the development of time-release pellets to extend the effectiveness of PZP. PZP has proven effective in reducing foaling rates, the population impacts of which are presently being determined.

8.3.2 Other Possible Fertility Control Tools

Other possible fertility control tools that could potentially be considered in the future include:

- Spaying mares.
- Vasectomizing studs.
- Use of IUDs.
- Use of GonaCon™.
- Use of SpayVac™.
- Use of other fertility control agents or sterilants.

8.3.2.1 Spaying (Mares)

Spaying mares involves major abdominal surgery, is risky, and requires good post-operative care. Spaying mares could be considered in the future if safe, effective and humane surgical methods and post-operative care procedures can be perfected for use on wild horses.

8.3.2.2 Vasectomies (Stallions)

Performing vasectomies on stallions is not a widely practiced procedure within veterinary medicine. Post-vasectomy, it is expected that studs would retain their stud-like behavior. By contrast, gelding studs (castration) is a routine veterinary procedure in both domestic and wild horses. However, geldings lose their stud-like behavior after a few months.

Vasectomized studs would be expected to continue to cover mares and keep them in a harem, but eventually most mares would be bred by an intact stallion. If this continued over several estrous cycles it could lead to extended foaling seasons and potentially an increase in foal mortality. Research shows that at 15-33 percent of foals are sired by non-harem stallions, making it unlikely that fertility control focused on males would be effective in slowing population growth (Bowling and Touchberry 1990, Kaseda and Kahlil 1996, Asa 1999). Further research is needed to perfect a safe technique for performing vasectomies in stallions and demonstrate whether this approach will reduce population growth rates.

8.3.2.3 Use of IUDs

Pilot studies using coil-type intrauterine devices (IUDs) and glass balls or marbles as IUDs have failed to demonstrate a long-lasting effect on conception in mares. In both instances, mares "slipped" the devices and became pregnant soon thereafter. The application of IUDs is further complicated by the difficulties associated with identifying a time window for application when mares are not pregnant.

8.3.2.4 Use of GonaCon™

GonaCon™ is an experimental fertility control vaccine that is being developed for potential use as a management tool for deer. Tests of the GnRH vaccine are ongoing in several States and countries, involving a wide range of wildlife and feral species, including horses. A research study conducted with estray horses in Nevada suggests GonaCon™ will reduce foaling rates for 1 year following treatment. At present, the effectiveness of GonaCon™ as a fertility control agent beyond one year appears similar to or less than that of PZP-22, suggesting limited potential for use of the product to reduce population growth rates over a longer period of time.

8.3.2.5 Use of SpayVac™

SpayVac™ is an experimental fertility control vaccine using PZP antigens and a novel liposome technology. It is easy to handle and administer. A single vaccination with SpayVac™ has maintained a high level of contraception throughout a 4-year study with estray horses in Nevada. However, there is currently no regulatory approval for the management or investigational use of

SpayVac™ through the EPA or FDA, and the product is not currently commercially available. SpayVac™ may have potential for use as an effective, longer-lasting fertility control agent in the future and could offer an alternative to spaying mares. However, additional research would be needed before it could be used on a population-management basis.

8.3.3 Population Estimation and Setting Population Goals

Aerial surveys rarely detect all WH&B within an HMA. As a result, population estimates must be developed using correction factors to account for WH&B not identified during the census. At present, research is being conducted on two techniques (simultaneous double-count and photo mark-resight) that will allow use of such correction factors.

8.3.4 Other Research

In the future, research may be conducted in other areas identified as research priorities, depending on need and funding. When other research needs are identified or research projects are proposed, they will be reviewed and evaluated by the National WH&B Research Advisory Team and recommendations will be made to the WH&B Division Chief.

GLOSSARY OF TERMS

Activity Plan – Examples of activity plans include Herd Management Area Plans (HMAPs) and Allotment Management Plans (AMPs). These plans lead to implementation decisions that usually describe multiple projects or management actions and apply best management practices to make progress toward attainment of Land Use Plan (LUP), Land Health Standards, or other resource objectives.

Adaptive Management – WH&B management is adjusted as indicated based on the results of monitoring and evaluation.

Adult Wild Horse – WH&B 1 year of age and older are considered adults. A foal is considered 1 year of age on January 1 of the year following its birth.

Adult Breeding Population - Wild horses within a population that are 1 year of age and older.

Aerial Survey – A method of counting WH&B using an aircraft. Aerial survey allows the BLM to obtain estimates of WH&B population size with associated confidence intervals.

Animal Unit (AU) - Wild horses 1 year of age and older count as 1 AU and burros 1 year of age and older count as 0.5 AU.

Animal Unit Month (AUM) – The amount of forage (approximately 800 pounds of air dried forage) necessary to sustain one adult horse or two burros for one month.

Appropriate Management Level (AML) - The number of adult horses or burros (expressed as a range with an upper and lower limit) to be managed within an HMA. Forage for WH&B (AUMs) is allocated based on the AML upper limit.

AML Range – The number of adult WH&B within which herd size will be allowed to fluctuate.

AML Upper Limit – The maximum number of WH&B that results in a thriving natural ecological balance (TNEB) and avoids a deterioration of the range. This number should be somewhere below the number that would cause damage to the range (refer to 118 IBLA 75).

AML Lower Limit – The number that allows the population to grow to the AML upper limit over 4-5 years, without the need for gathers to remove excess WH&B in the interim.

Authorized Officer – Any employee of the BLM to whom authority has been delegated to perform the duties described in this Handbook (refer to BLM Manual 1203 for a further explanation of delegation of authority).

Census – A complete count of the total WH&B population within an area. Because aerial surveys do not usually detect all WH&B within an HMA, a true census is usually not possible. Better population estimates are developed using correction factors to account for WH&B not seen during the survey (i.e., sightability correction factors).

Considered Comparably - During the LUP process, WH&B are considered in the same manner as other resource values (e.g., cultural, historic, scenic, rangelands, timber, and minerals).

Emergency – An unexpected event that threatens the health and welfare of a WH&B population and/or its habitat. Examples include fire, insect infestation, disease or other events of a catastrophic and unanticipated nature.

Escalating Problems - Conditions that deteriorate over time. The key indicators are a decline in the amount of forage or water available for WH&B use, with negative impacts to rangeland health and, ultimately, animal condition. Causal factors are normally drought and/or animal numbers in excess of AML. These situations can be detected in advance and are managed through the normal planning process.

Evaluation (LUP Evaluation) – The process of reviewing the land use plan and periodic plan monitoring reports to determine whether the decisions and NEPA analysis are still valid and whether the plan is being implemented.

Evaluation (HMAP Evaluation) – Periodic review of herd management area plans (HMAPs) to determine if the selected management practices were implemented as planned (answers the question "Did we do it?") and whether or not the plan is effective in making progress toward established habitat and population management objectives (answers the question "Did it work?").

Excess Animals – Wild, free-roaming horses or burros which have been removed or which must be removed from in order to preserve and maintain a thriving natural ecological balance and multiple-use relationship in an area.

Fertility Control – A tool to decrease fertility and which, when implemented, reduces (slows) population growth rates and extends the gather cycle.

Free-Roaming – WH&B are able to move without restriction by fences or other barriers within a HMA.

Goal – A broad statement of a desired outcome.

Genetic Diversity – The absence of inbreeding depression as monitored through an established baseline and periodic reassessment. This represents an expression of the genetic health of an individual animal or the population.

Herd (Reproducing) – One or more stallions and their mares and foals.

Herd Area (HA) - Geographic areas of the public lands identified as habitat used by WH&B at the time the WFRHBA was enacted (12/15/1971).

Herd Management Area (HMA) – May be established in those HAs within which WH&B can be managed for the long term. HMAs are designated through the LUP process for the

maintenance of WH&B herds. In delineating each HMA, the authorized officer shall consider the appropriate management level (AML) for the herd, the habitat requirements of the animals, the relationships with other uses of the public and adjacent private lands, and the constraints contained in 43 CFR 4710.4.

Herd Management Area Plan (HMAP) – An HMAP establishes management actions and short- and long-term management and monitoring objectives for a specific WH&B herd and its habitat. HMAPs assist the authorized officer in tracking progress toward achieving LUP goals. They are prepared under authority of 43 CFR 4710.3-1. An HMAP can be prepared for an individual HMA or a complex of HMAs.

Implementation Decision – Decisions that make progress or take action toward achieving LUP goals and objectives.

Implementation Plan – Refer to Activity Plan above.

Land Use Plan (LUP) – LUPs provide (by tracts or areas) for the use of public lands. LUPs are prepared in accordance with established land use planning procedures in 43 CFR 1600 and pursuant to FLPMA. They establish goals and objectives (desired outcomes), identify the management actions needed to achieve the desired outcomes, and identify the allowable uses of the public lands.

Manage Principally but not Exclusively – An HMA may be considered for designation as a wild horse or burro range when there is significant public value present, such as unique characteristics in a herd or an outstanding opportunity for public viewing. These HMAs may be managed principally, but not exclusively, for wild horse or burro herds.

Minimal Feasible Level of Management - The minimum number of habitat or population management tools or actions necessary to attain the objectives identified in approved LUPs and HMAPs for a HMA or HMA complex.

Monitoring – The process of collecting and analyzing the data necessary to evaluate existing management and determine whether progress is being made toward attaining established habitat and population management goals and objectives.

Non-Reproducing Wild Horses – An HMA composed, in whole or in part, of sterilized wild horses (either stallions or mares) to aid in controlling on the range population numbers.

Objective(s) – A description of the desired outcome of a management decision. Objectives are specific, measurable, achievable/attainable, reasonable/relevant, and progress can be quantified within established timeframes for achievement (SMART).

Plan Monitoring – The process of tracking land use plan implementation, including collecting and assessing the data or information necessary to evaluate the effectiveness of land use planning decisions.

Population Growth Rates – Represent the net effect of births and deaths in any given year. The BLM reports annual population numbers as of February 28th.

Range – The amount of land necessary to sustain an existing herd or herds of wild free-roaming horses and burros, which does not exceed their known territorial limits.

Resource Management Plan – see LUP above.

Self-Sustaining – The ability of reproducing herds of wild horses and burros to maintain themselves in a healthy condition and to produce healthy foals.

Standards for Land Health – Standards are statements of physical and biological condition or degree of function required for healthy sustainable rangelands. Achieving or making significant progress towards these functions and conditions is required of all uses of public lands. Historical data, when available, should be utilized when assessing standards.

Standard Operating Procedures – The Bureau follows standardized methods of operation which have been developed over time to assure the safe, effective, and humane handling and treatment of WH&B.

Thriving Natural Ecological Balance (TNEB) – WH&B are managed in a manner that assures significant progress is made toward achieving the Land Health Standards for upland vegetation and riparian plant communities, watershed function, and habitat quality for animal populations, as well as other site-specific or landscape-level objectives, including those necessary to protect and manage Threatened, Endangered, and Sensitive Species.

Utilization – The portion of annual forage production that has been consumed by herbivores (WH&B, domestic livestock, wildlife, and insects). The term is also used to refer to the pattern of such use.

WH&B Range – A HMA which meets the special criteria defined in H-1601-1, Land Use Planning Handbook. These include unique herd characteristics, viewing opportunities, unique landscape, significant public demand or other reasons. WH&B Ranges are managed principally, but not necessarily exclusively, for WH&B.

Wild Free-Roaming Horses and Burros – All unbranded and unclaimed horses and burros that use public lands within 10 contiguous Western States as all or part of their habitat, or that have been removed from these lands by the authorized officer, or have been born of wild horses or burros in authorized BLM facilities, but have not lost their status under the WFRHBA (16 USC § 1332 (f)).

APPENDIX 1 - Genetics Data and Hair Sample Collection Instructions

Analysis of DNA to determine genetic diversity of wild horse and burro (WH&B) herds is currently being done using hair samples rather than blood samples. Unless there is a previously recognized concern regarding low genetic diversity in a particular herd, it is not necessary to collect genetic information at every gather. Typical herds should be sampled every other gather. A new baseline does not need to be established through hair analysis if blood analysis has already been completed. Please follow the instructions below for collecting hair samples. Call BLM's National WH&B Research Coordinator if you have any questions.

While it is preferable to sample release horses, you may sample removed horses if necessary. In complexes or HMAs where separate breeding populations are suspected, WH&B in each distinct population should be sampled separately. Do not mix samples from different horses or different breeding populations. The minimum sample size is 25 animals or 25 percent of the post-gather population, not to exceed 100 animals per population. Samples should be collected from males and females in the same approximate ratio as the population. Animals of any age class may be sampled. Burros should be sampled in the same manner as horses.

1. You will need one plain white paper envelope (a white #10 business envelope works best) for each horse. DO NOT use plastic or zip-lock bags and DO NOT use plastic coated envelopes or envelopes with windows in them.

2. Hair samples must be obtained by pulling the hair out by the root NOT cutting or shaving it off the horse. This is because the DNA is in the root follicle not the hair itself. Mane hair will work, but for foals or young horses you may need to obtain tail hair. Please submit about 30 hairs per animal. A bundle of 30 hairs is about the diameter of a pencil.

The easiest way to pull a good sample is to grasp a bundle of hair and wrap it around a clean mane comb or hoof pick. Holding the bundle close to the neck, pull **straight out** firmly. Foal hair is more brittle and tends to break off. If you are having trouble getting hair with the root attached try obtaining a tail hair sample instead.

(James Sturdivant – The Jockey Club, modified with permission)

3. Check that you have the hair roots or hair bulbs attached to the hair at the base. They look, and feel like little bumps on the end of each hair.

Keep the hair in a loose bundle pointed in one direction or twist it together and place it in an envelope. You can cut off excess hair and leave only a few inches with the hair root attached to put in the envelope if that is easier.

4. Seal the envelope and **write the sample number on the envelope.**

Also write the sample number, color, sex and age of the horse on the data collection sheet. If animals cannot be aged in years, at a minimum record adult, yearling or foal. Be sure to keep stray hairs out of the comb and off your clothes so they don't contaminate the next sample.

Please NOTE: it is best to sample when the hair is dry. If you need to sample when it is raining or the horses are wet, then DO use zip-lock bags for each sample AND keep the samples cool not frozen (refrigerate, then ship the samples with cold packs).

Please fill out the top of the form completely, including the HMA name, HMA number and the date the sample was collected.

Within 3 days after hair collection, send a copy of the data collection form to:

Attn: Research Coordinator, National Program Office-Reno

FEDEX the samples, to arrive on a weekday not the weekend **with the Data Collection Sheet to Dr. Gus Cothran, address below:**

APPENDIX 3 - AML Establishment and Adjustment Process

AML decisions determine the number of WH&B to be managed within an HMA or complex of HMAs. AML is expressed as a population range with an upper and lower limit. The AML upper limit is the number of WH&B which results in a TNEB and avoids a deterioration of the range. The AML lower limit is normally set at a number that allows the population to grow to the upper limit over a 4-5 year period, without any interim gathers to remove excess WH&B. See Chapter 4.

A multi-tiered analysis process should be used to establish and adjust the appropriate management level (AML) of WH&B.

- ❒ **Tier One**: determine whether the four essential habitat components (forage, water, cover and space) are present in sufficient amounts to sustain healthy WH&B populations and healthy rangelands over the long-term.

- ❒ **Tier Two**: determine the amount of sustainable forage available for WH&B use.

- ❒ **Tier Three**: determine whether or not the projected WH&B herd size is sufficient to maintain genetically diverse WH&B populations (i.e., avoid inbreeding depression).

Should the Tier One analysis determine that one or more of the essential habitat components is insufficient to maintain a healthy WH&B population and healthy rangelands; the authorized officer should consider amending or revising the LUP to remove the area's designation as an HMA.

Tier 1

Determine if the four essential habitat components (forage, water, cover, and space) are present in sufficient amounts to sustain healthy WH&B populations and healthy rangelands over the long-term. In making this determination, the most limiting factor(s) within the HMA should be considered. In some HMAs, the most limiting factor may be:

- The water available for WH&B use.
- The limited habitat available for WH&B use on either the summer or winter range, in HMAs with seasonal ranges.
- The naturally occurring, low productive capability of the dominant ecological sites.
- The low ecological status of key WH&B use areas.
- Low annual rainfall or extended periods of drought.

The essential habitat components must be located on public lands within the HMA boundary. If forage or water located on private lands within the HMA is needed to maintain healthy WH&B populations, a written agreement with the private landowner allowing use by WH&B is required. In the absence of private landowner agreement, the forage and water on private lands is not available for use by WH&B and may not be included when establishing or adjusting AML.

Forage

The amount of forage available for WH&B use is expressed in animal unit months (AUMs). One AUM is defined as the amount of forage necessary to sustain one adult horse or two adult burros for one month (or approximately 800 pounds of air dry forage). Twelve AUMs of forage are needed to support one wild horse or two adult burros for one year.

As a **starting point**, the amount of sustainable forage available for WH&B use may be determined based on the results of utilization monitoring and use pattern mapping for the years evaluated. A determination of forage availability should not be based on the results of only one year's monitoring data. A minimum of three to five years of monitoring data is preferred. This is because forage production can vary substantially from year to year based on the timing and amount of precipitation received, among other factors. Under the same level of grazing, use pattern mapping may indicate light to moderate utilization during above normal precipitation years, yet indicate heavy or severe utilization during below normal precipitation years.

The nature of the forage (i.e., perennial vs. annual) should also be considered. While annual forage may be available to support WH&B use during years with normal or above normal precipitation, it may be greatly reduced during below average precipitation years. As a result, annual forage is not typically used to support or justify WH&B numbers within a HMA. Within perennial ranges, the production of perennial species may also be greatly reduced during drought, and the production of annual grasses and forbs may be largely absent.

The flexibility to remove WH&B in below average forage years, or to move the animals to another area, can be constrained by funding, contractor capability, facility space, or animal behavior. To prevent range damage or adverse impacts to animal health, the upper limit of AML for WH&B should be established in consideration of the most limiting forage (or water) production years.

Other Considerations

1. Situations in which the Land Health Standards are achieved but population inventory indicates more WH&B are present than expected. These situations may indicate additional forage is present to support use by higher numbers of WH&B, wildlife, or livestock, consistent with LUP guidance.

2. Situations in which deteriorated land health conditions exist but population inventory indicates the number of WH&B is the same or lower than expected. These situations may indicate there is less forage available to support the existing use by WH&B, wildlife, or livestock, and that a reduction in the allowable use may be needed, consistent with LUP guidance.

The number of WH&B which can be sustained based on the available forage is determined in **Tier Two.** To determine if there is sufficient forage to sustain long-term WH&B:

- Analyze utilization data, use pattern mapping, and/or production, ecological site condition (ESI), trend, frequency, precipitation (weather), and indicators of land health.

- Determine the AUMs of actual use by WH&B for each of the evaluation years. (Calculate the AUMs of actual WH&B use based on population estimates derived from aerial surveys. You can also project actual use by WH&B using previous population estimates together with herd's average annual population growth rate.)
- Identify key WH&B use areas (distribution). Calculate carrying capacity on the basis of the key use areas (primary range).

Water

The amount of water available for WH&B use is generally based on public, natural waters (i.e., water occurring on private lands is not considered unless a written agreement with the private landowner is obtained). Water availability during drought conditions is also considered. Sufficient water for WH&B must be available during drought to achieve and maintain a thriving natural ecological balance and multiple use relationship on the public lands.

In determining the amount of water available for WH&B use, a thorough inventory of the available public, natural water resources is needed. Developed and man-made waters should also be inventoried if they are available for WH&B use (i.e., BLM holds the necessary water rights and WH&B access to the water can be depended upon over the long-term). The water resources inventory should include the name, location, and flow (in gallons per minute or cubic feet per second). Wild horses require a minimum of 10 gallons of available water per animal per day (15 gallons per day is not unusual during the hot, dry summer months) while burros require about 5 gallons available per animal per day. The analysis of available water should also be based on the most limiting season of the year (i.e., generally summer when flows are reduced).

Cover and Space

A recurring pattern of WH&B movement out of the HMA to access forage, water, or thermal or hiding cover is an indication the HMA cannot sustain year-long WH&B use. If one or more of the key habitat components is missing, the HMA should be considered as unsuitable for year-long use by WH&B. In these situations, the authorized officer should consider amending or revising the LUP to remove the area's designation as an HMA. An exception would be two or more HMAs which adjoin and are managed as a complex of HMAs, or HMAs which adjoin Forest Service wild horse territories (WHT) that can be managed as a complex.

The results of the **Tier One** analysis may be summarized in a simple table (see example Table 3.1 below). The table should be followed by a detailed description of the analysis and the rationale used in making the determination that a key habitat component either is (or is not) sufficient to support healthy WH&B populations and healthy rangelands over the long-term.

Table 3.1
Sufficient Forage, Water, Cover and Space

HMA	Forage		Water		Cover		Space	
	Sufficient	Insufficient	Sufficient	Insufficient	Sufficient	Insufficient	Sufficient	Insufficient
HMA 1	X			X	X		X	
HMA 2		X		X	X		X	
HMA 3	X			X	X		X	

Tier 2

Determine the AUMs of sustainable forage available for WH&B use. Based on the desired level of utilization, propose an AML for WH&B (expressed as a range with an upper and lower limit).

Forage availability should be determined based on in-depth analysis of rangeland monitoring data. As a first step, monitoring data should be reviewed to determine if Land Health Standards or other site-specific vegetation management objectives are being met. If standards and objectives are being met, WH&B population estimates are then examined to determine the range in number of WH&B using the HMA during the evaluation years. The upper values are used to establish AML when no land health issues occur.

In HMAs where Land Health Standards or other objectives are not being achieved, WH&B use should be examined to determine if this level of use has contributed to or is the causal factor for the standards or objectives not being met (or only partly met). When standards or objectives are not being met and WH&B use is a contributing (or causal) factor, AML is proposed based on the estimated number of WH&B present relative to the level of forage utilization that is occurring (i.e., AML would be established at a number below that which has contributed to the standards or objectives not being met). The need for frequent emergency removals of WH&B due to lack of forage and/or water or the emigration of WH&B out of the HMA due to population size or concentration levels may also be a consideration in proposing AML for WH&B.

The sustainable forage (carrying capacity) available for WH&B use within a HMA is determined pending detailed analysis of utilization data and use pattern mapping for all users. For each evaluation year, determine the following: (1) weighted average utilization, (2) potential carrying capacity, and (3) the proposed carrying capacity. An example for the Mojave Desert ecosystem follows.

Example – Determining Sustainable Forage Available for WH&B Use (Mojave Desert Ecosystem)

The following example can be used to assist with establishing and/or adjusting AML for WH&B use. To determine if there is sufficient forage to sustain long-term WH&B use, analysis of utilization data, use pattern mapping, and/or production, ecological site condition, trend, frequency or other indicators of rangeland health is necessary.

Selection of Allowable Use Criteria

The recommended allowable utilization by all herbivores under year-round use within the Mojave Desert ecosystem is 25-35 percent of the current year's forage production.

WH&B use will be limited to 25 percent of current year's production on key vegetation species as measured at seed dissemination for these species.

Rationale: Within the Mojave Desert ecosystem, allowable use levels of 25 percent are recommended for areas in poor ecological condition or for areas grazed during the growing season. Allowable use levels of 35 percent are recommended for areas in good ecological condition or for areas grazed during the dormant season. Allowable use is established at 25 percent for this HMA due to year-round grazing by WH&B as well as a number of areas in poor ecological condition.

Determine Weighted Average Forage Utilization

Deriving a weighted average utilization from use pattern maps generally provides a more representative picture of the forage use that has occurred throughout the HMA and leads to a more accurate estimate of carrying capacity. To derive a weighted average utilization for the HMA, determine the number of acres within the HMA which received moderate, heavy or severe utilization for each evaluation year.[3] Refer to BLM Technical Reference 4400-7 for additional information.

The weighted average use is calculated by multiplying the number of acres by the mid-point of the utilization category (example: moderate use is classified as 41-60 percent, therefore, 50 percent is the mid-point used in the calculation).

Data used in the example carrying capacity analysis outlined below includes: utilization data, use pattern mapping data, actual livestock use information, and WH&B population estimates.

[3] To protect rangeland health over the long-term, consider WH&B use only on the primary range when deriving a weighted average utilization. Primary range is defined as the areas which animals (WH&B) prefer to use when management is limited (refer to Glossary of Terms Used in Range Management, 4th Edition, Published by Society for Range Management, 1998). Secondary range is defined as range which is not ordinarily used until the primary range has been overused. Therefore, areas receiving slight or light use or that are unused should not be considered when deriving a weighted average utilization.

Weighted Average Utilization =

(Moderate use acres*50 percent) + (Heavy use acres*70 percent) + (Severe use acres*90 percent)

Analyze the total acres of moderate, heavy, and severe use.

1995 $\frac{(19639*50\text{ percent}) + (34351*70\text{ percent})}{53{,}990}$ = 63 percent

1996 $\frac{(8023*50\text{ percent}) + (48957*70\text{ percent}) + (9885*90\text{ percent})}{66{,}865}$ = 71 percent

1997 $\frac{(3081*50\text{ percent}) + (22888*70\text{ percent})}{25{,}969}$ = 68 percent

1999 $\frac{(5627*50\text{ percent}) + (3696*70\text{ percent})}{9{,}323}$ = 58 percent

2000 $\frac{(4344*50\text{ percent}) + (4386*70\text{ percent})}{8{,}730}$ = 60 percent

2002 $\frac{(5627*50\text{ percent}) + (3696*70\text{ percent})}{9{,}323}$ = 58 percent

2004 $\frac{(4395*50\text{ percent}) + (7933*70\text{ percent})}{12{,}328}$ = 63 percent

The example below demonstrates the impact of variable precipitation (and forage production) on actual forage utilization and the desired carrying capacity.

Potential Carrying Capacity =

Average use in AUMs (of cattle or horse use)*25 percent Allowable Use Objective
Weighted Average Utilization

Year	Average Use (AUMs)		Effective Precipitation
1995	3000 AUMs*25 percent / 63 percent	= 1190 AUMs	Above Average
1996	600 AUMs*25 percent / 71 percent	= 211 AUMs	Severe Drought
1997	444 AUMs*25 percent / 68 percent	= 163 AUMs	Severe Drought
1999	600 AUMs*25 percent / 58 percent	= 259 AUMs	Severe Drought
2000	1440 AUMs*25 percent / 60 percent	= 600 AUMs	Slightly Below Average
2002	1632 AUMs*25 percent / 58 percent	= 703 AUMs	Average
2004	3576 AUMs*25 percent / 63 percent	= 1419 AUMs	Well Above Average

Proposed Carrying Capacity =

In the example above, the carrying capacity would be set in consideration of the driest years in order to prevent damage to the range or adverse impacts to animal health.

211 (1996) +163 (1997) +259 (1999) +600 (2000) +703AUMs (2002) = 387 AUMs
5 (# years of data)

Proposed AML =

387 AUMs (Desired Carrying Capacity) = 32 cattle or wild horses
12 months

Or:

$$\frac{\text{387 AUMs (Desired Carrying Capacity)}}{\text{6 months}} = 65 \text{ burros}$$

***Discussion*:**

- Allocation of the forage between WH&B, wildlife and domestic livestock would be made after site-specific NEPA analysis is completed.

- In the example above, the upper limit of the AML range for wild horses was calculated by dividing the proposed carrying capacity for the HMA (expressed in AUMs) by 12 months.

- The upper limit of the AML range for burros was calculated by dividing the proposed carrying capacity for the HMA by 6 months (an adult burro is equivalent to only 0.5 AU).

- The lower limit of the AML range would be determined based on the herd's average annual growth rate (i.e., the lower limit will normally be set at a number that allows the herd to grow to the upper limit over a 4-5 year period without the need for gathers to remove excess WH&B in the interim).

Tier 3

Determine whether or not the WH&B herd size proposed in Tier Two is sufficient to maintain genetically diverse WH&B populations (i.e., avoid inbreeding depression). To avoid inbreeding depression in wild horse populations, a minimum herd size of 50 effective breeding animals (a total population size of about 150-200 animals) is recommended. An effective breeding size for burro herds has not yet been determined.

If the herd size proposed in Tier Two is not sufficient to maintain genetically diverse WH&B populations, determine if there is WH&B interchange between the HMA and other adjacent HMAs or WHTs and whether this interchange would be sufficient to maintain genetic diversity (avoid inbreeding depression). Genetic diversity baseline or monitoring information can be used to evaluate whether WH&B interchange between HMAs is occurring.

If the proposed herd size is less than 150 animals and the HMA is isolated with limited potential for WH&B egress/ingress, possible management actions which could be considered as part of an appropriate site-specific NEPA analysis could include:

1. Removing the area's designation as an HMA through LUP and returning it to HA status.
2. Maximizing the number of breeding age WH&B in the herd (animals age 6-10 years).
3. Adjusting the sex ratio to favor males to encourage formation of additional breeding harems.
4. Introducing 1-2 young mares from outside the HMA every generation (about every 10 years). Introduced animals should come from herds living in similar environmental conditions.

Documentation

The results of the multi-tiered analysis should be documented in an HMA (AML) Evaluation Report. The completed report should be provided to the affected and interested public for a 30-day review and comment period (e.g., public scoping). The management evaluation report is not a decision subject to administrative appeal. However, once the decision is made, the Evaluation Report is part of the administrative record for that decision.

Following public scoping, a site-specific environmental analysis should be completed to analyze the environmental impacts associated with the Proposed AML and any alternatives. As part of the environmental analysis, summarize the results of public scoping and document how BLM used the comments in preparing the environmental assessment (or EIS).

Based on the analysis of potential environmental impacts, the authorized officer will determine whether to prepare an Environmental Impact Statement (EIS) or issue a Decision Record and Finding of No Significant Impact (FONSI). A FONSI documents why implementation of the selected AML will not result in environmental impacts that significantly affect the quality of the human environment. Or, if an EIS has been prepared, the authorized officer's decision will be documented in a Record of Decision.

Administrative Review

AML decisions are subject to administrative review (appeal) pursuant to 43 CFR Part 4.

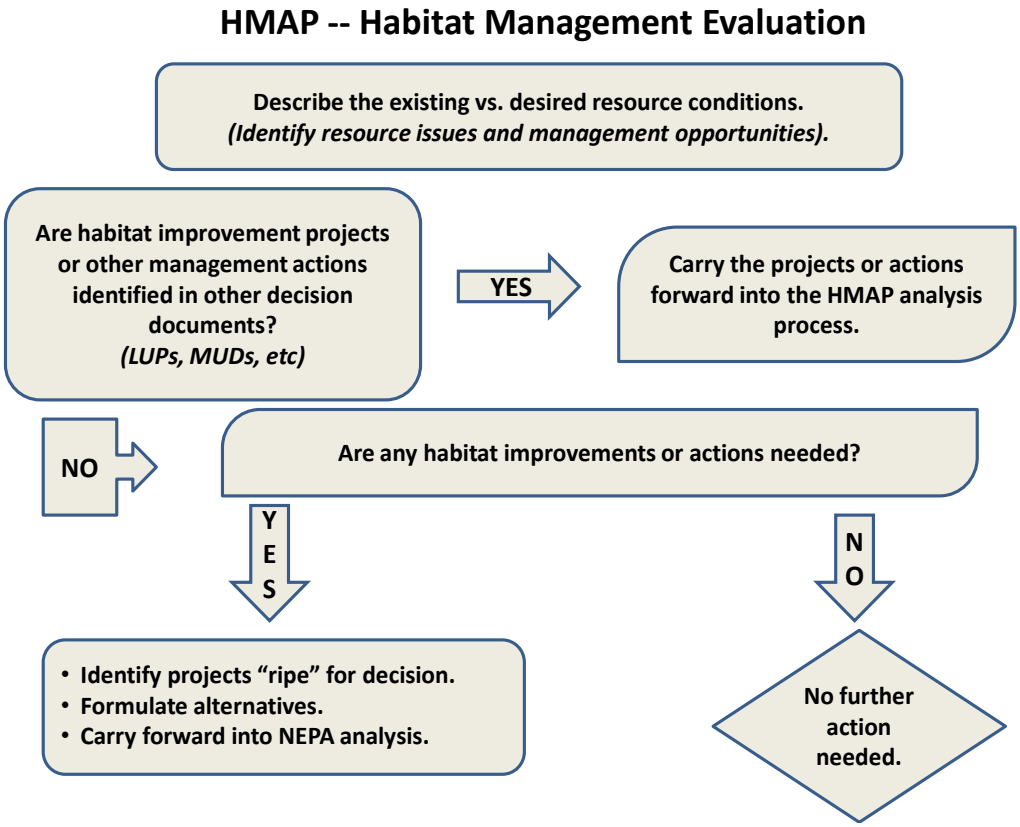
APPENDIX 4 - Herd Management Area Planning

Herd management area plans (HMAPs) establish the management actions and the short and long-term management and monitoring objectives for WH&B herds and their habitat. Once established with public involvement through site-specific NEPA analysis and decision, the objectives guide management of the HMA or complex over the life of the plan.

Management Evaluation

Typically, the first step in the HMAP analysis process should be to evaluate existing management. The existing vs. the desired condition of the both the herd and its habitat are examined during the evaluation. Refer to Figures 4.1 and 4.2.

Figure 4.1
Habitat Management Evaluation



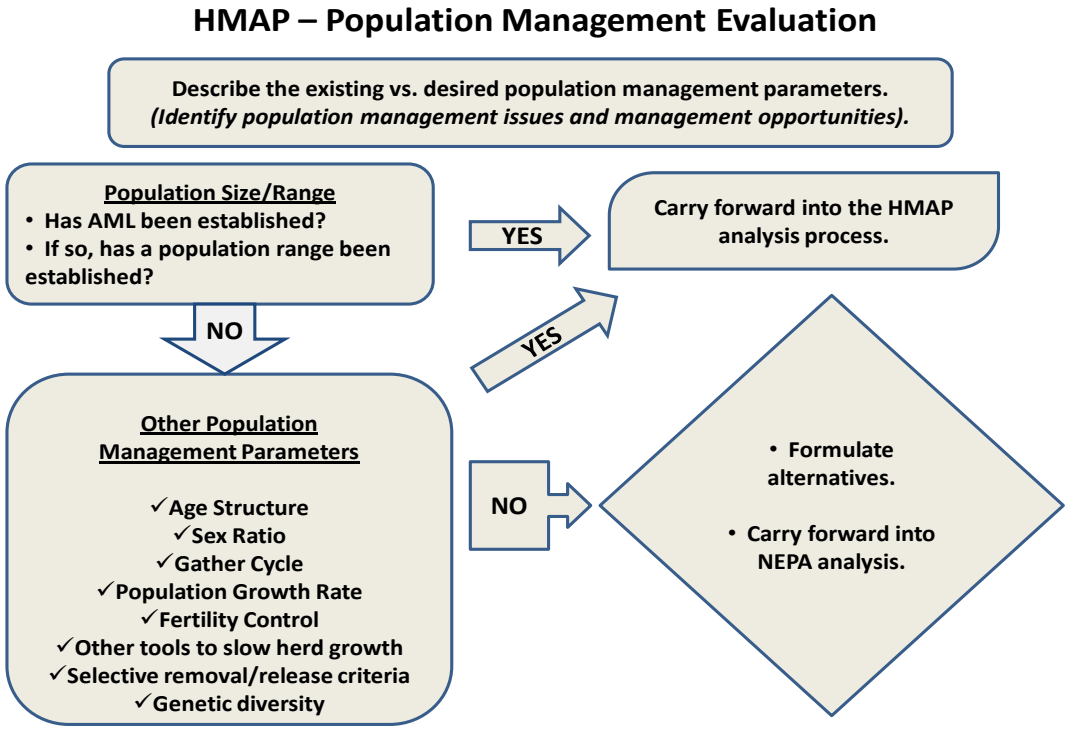


Figure 4.2
Population Management Evaluation

At the conclusion of the management evaluation, a report is prepared and provided to the public for a 30-day review and comment period (public scoping). The management evaluation report is not a decision subject to administrative appeal. Rather, the report documents the key issues identified as a result of the management evaluation. A range of the possible management alternatives (Proposed Action and Alternatives) which could address/resolve the identified issues may also be identified.

NEPA Analysis and Decision
The next step in the HMAP analysis process would be to analyze the potential environmental consequences which could result from implementation of the Proposed Action or Alternatives through completion of a site-specific environmental analysis (NEPA).

To prepare a concise environmental assessment (EA), site-specific management, monitoring and implementation objectives can be displayed in a tabular format within the environmental assessment. Refer to the example which follows.

Example – Documentation of the No Action Alternative in the HMAP EA

Alternative One: No Action Alternative, Continue Existing Management
Under Alternative 1 (No Action), the HMA would continue to be managed as a range of 150-250 wild horses as follows:

- The sex ratio of the animals released back to the range following future gathers would be about 34 percent males and 64 percent females.
- Existing monitoring, including utilization, forage condition, water availability, animal health and periodic population estimates and sampling for genetic diversity (inbreeding) would occur.
- AML would be adjusted, as needed, based on in-depth analysis of resource monitoring data.
- Fertility control would be applied to mares released back to the range following future gathers.

Table 4.1
No Action Alternative (Continue Existing Management) in HMAP Format

Management Objective(s)	Monitoring Objective(s)	Implementation Objective(s)
A. Control Population Numbers Manage the wild horse population within the established AML range to protect the range from the deterioration associated with overpopulation.	Aerially estimate populations a minimum of once every 3-4 years. Determine population number and average annual herd growth rate.	Schedule gathers to remove excess wild horses when (1) the population reaches or exceeds the AML upper limit (about every 3 years), or (2) when forage utilization exceeds 50 percent of current year's growth in ½-2/3 of the key areas; or (3) when animal health/condition is at risk.
B. Assure Land Health Limit utilization by all herbivores to 50 percent of the current year's above ground primary production for key grasses and 45 percent for key shrubs and forbs.	• Locate key monitoring areas within the HMA. • Establish baseline trend studies using the frequency sampling procedures outlined in the (cite applicable BLM Technical Reference or Handbook). • Measure utilization at key areas and complete use pattern mapping annually.	Re-adjust AML or identify management actions to address resolve land health issues, as needed/appropriate, based on results of land health monitoring.

Based on the analysis of potential environmental consequences, the authorized officer will determine whether to prepare an EIS or issue a Decision Record and FONSI.

HMAP
As a final step and to facilitate on-the-ground implementation, the selected management strategy (selected alternative), together with the habitat and population management, monitoring and implementation objectives are documented in HMAP format. The HMAP is included as an attachment to the authorized officer's final decision.

HMAP Format

1. Introduction. Briefly summarize the relevant background information.

2. Selected Management Alternative. Briefly summarize the selected management strategy/alternative as outlined in the EA, together with the site-specific habitat and population management objectives and management actions.

3. Monitoring and Evaluation Plan.

4. Project Tracking and Implementation Schedule.

The Monitoring Plan and Tracking Log/Project Implementation Schedule may also be prepared in a tabular format. See the examples which follow.

Table 4.2
Example -- Monitoring Plan

Item	How	Who	When	Actions to Take (Adaptive Management)
Population Management Monitoring				
Manage wild horse populations within the established AML range.	Aerial survey flights following established protocols. Simultaneous double count method or other approved protocol pending population estimation research results & recommendation.	FO WH&B Specialist	Aerial population estimates a minimum of every 3 years, i.e., 2010, 2013, etc.	Schedule gathers to remove excess wild horses when (1) the population reaches or exceeds the AML upper limit (about every 3 years), or (2) when forage utilization exceeds 50 percent of current year's growth in ½-2/3 of the key areas; or (3) when animal health/condition is at risk.
Habitat Management Monitoring				
Limit utilization by all herbivores to 50 percent of the current year's above ground primary production for key grasses and 45 percent for key shrubs and forbs.	Measure utilization at key areas and complete use pattern mapping annually.	FO WH&B Specialist	Annually (October)	Re-adjust AML or identify management actions to address resolve rangeland health issues, as needed/appropriate, based on results of rangeland health monitoring.

1.0 Purpose of and Need for Action

1.1 Background

This Environmental Assessment (EA) is a site-specific analysis of the potential impacts that could result with the implementation of the Proposed Action or alternatives to the Proposed Action. Preparation of an EA assists the BLM authorized officer to determine whether to prepare an Environmental Impact Statement (EIS) if significant impacts could result, or a Finding of No Significant Impact (FONSI) if no significant impacts are expected.

The Barren Valley Complex comprises three Herd Management Areas (HMAs) in southeastern Oregon. Historically, the HMAs have been gathered both simultaneously and separately. Gathering the HMAs separately was not always successful due to wild horses crossing into adjoining HMAs during gather operations, therefore, the HMAs have been designated as a complex to be managed complete gather operations simultaneously.

Coyote Lake/Alvord-Tule Springs HMA comprises about 559,400 acres of public land. The HMA is located in Malheur and Harney Counties, west of Burns Junction, Oregon and east of Fields, Oregon (Map 1). The AML for wild horses within the HMA of 198-390 wild horses was reaffirmed in the Southeast Oregon Resource Management Plan Record of Decision (SEORMP/ROD, 2002). The HMA was last gathered in November 2008. The BLM is proposing to gather about 220 wild horses and remove approximately 50 excess wild horses from within and outside the Coyote Lake/Alvord-Tule Springs HMA beginning in about September 2011. One hundred ninety-eight wild horses would remain in the HMA after the gather; of these, about 80 would be mares treated with fertility control and about 120 would be studs or geldings to adjust the sex ratio and slow population growth.

The Sheepshead/Heath Creek HMA comprises about 204,500 acres of public land. The HMA is located in Malheur and Harney Counties, immediately northwest of Burns Junction, Oregon (Map 1). The AML for wild horses within the HMA is 161-302 wild horses. The AML was reaffirmed in the Andrews Management Unit Record of Decision and Resource Management Plan (AMURMP/ROD, 2005). The HMA was last gathered in November 2008. The BLM is proposing to gather about 350 wild horses and remove approximately 200 excess wild horses from within and outside the Sheepshead/Heath Creek HMA beginning in about September 2011. One hundred sixty-one wild horses would remain in the HMA after the gather; of these, about 60 would be mares treated with fertility control and about 100 would be studs or geldings to adjust the sex ratio and slow population growth.

The Sand Springs HMA comprises about 192,524 acres of public land. The HMA is located in Malheur County, immediately northeast of Burns Junction, Oregon and east of Highway 78 (Map 1). The AML for wild horses within the HMA is 100-200 wild horses. The AML was established in Southern Malheur Management Framework Plan (MFP) (1975) and was reaffirmed in the SEORMP/ROD (2002). The HMA was last gathered in September 2006. Currently, the numbers of wild horses residing in Sand Springs HMA is slightly below the low end of AML, therefore, the BLM is proposing to gather about 80 wild horses and remove only those animals that cross into Sand Springs HMA from Sheepshead/Heath Creek HMA during gather operations beginning in September 2011. There have also been approximately 25 wild horses observed outside of the Sand Springs HMA on public lands not designated as a herd area. Any wild horses residing outside the Sand Springs HMA would be gathered and removed. The current population of approximately 90 wild horses would remain in the HMA after the gather; of these, about 40 would be mares treated with fertility control and about 60 would be studs or geldings to adjust the sex ratio and slow population growth.

Since the previous gather in 2008, wild horses have concentrated in the Sheepshead/Heath Creek HMA and in Red Mountain North Pasture of the Coyote Lake/Alvord-Tule Springs HMA. There has also been movement into the Sand Springs HMA do to overcrowding in the Sheepshead/Heath Creek HMA. Based upon all information available at this time, the BLM has determined that approximately 250 excess wild horses exist within the Complex and need to be removed. In addition, approximately 25 wild horses exist south of the Sand Springs HMA that need to be gathered and removed. This assessment is based on the following factors including, but not limited to:

- An estimated population of 700 wild horses exists in the Barren Valley Complex in 2011 with approximately 200 horses in excess of the AML lower limits in Sheepshead/Heath Creek HMA and approximately 50 horses in excess of the AML lower limits in Coyote Lake/Alvord-Tule Springs HMA.
- Use by the approximately 25 wild horses residing south of the Sand Springs HMA is not within a herd area and does not comply with existing land use plans.
- Use by wild horses in Sheepshead/Heath Creek HMA is exceeding the maximum forage allocated to their use by approximately 10 - 30% in 2011.
- Riparian monitoring completed in 2008 and 2010 documents severe utilization of forage within riparian habitats, and extensive trampling and trailing damage by wild horses in the entire complex, but especially in Sheepshead/Heath Creek HMA and Red Mountain North Pasture of the Coyote Lake/Alvord-Tule Springs HMA.

1.2 Purpose of and Need for Action

The purpose and need for the proposed action is to meet the established objectives and goals of the SEORMP/ROD and AMURMP/ROD by maintaining the AML for the HMAs in the Barren Valley Complex (SEORMP/ROD, 2002, 55-57 and AMURMP/ROD, 2005 50-53). The purpose of the action is to gather and remove excess wild horses from the Barren Valley Complex. This action is necessary to maintain a thriving natural ecological balance which protects public land resources from deterioration. During the most recent field monitoring in 2010 and 2011, the wild horse population in the complex is concentrated in the Sheepshead/Heath Creek HMA and Red Mountain North Pasture of Coyote Lake/Alvord-Tule Springs HMA. This has created heavy to severe utilization of riparian and upland vegetation in and adjacent to perennial streams, springs, and reservoirs. Resource damage is occurring in some areas of the HMA due to the current overpopulation of wild horses, and is likely to continue to occur as well as increase without immediate action.

This action is needed in order to achieve and maintain a population size within the established AML, protect rangeland resources from further deterioration associated with the current overpopulation, and restore a thriving natural ecological balance and multiple use relationship on public lands in the area consistent with the provisions of Section 3(b)(2) of the Wild Free-Roaming Horses and Burros Act (WFRHBA) of 1971.

1.3 Land Use Plan Conformance

The Action Alternatives are tiered to the SEORMP/FEIS (2001, Chapter 3 242-246) and AMURMP/FEIS (2004, Chapter 4 171-183) and are in conformance with decisions made in the SEORMP/ROD (2002, 55-57) and AMURMP/ROD (2005, 50-53). Objectives identified for wild horse herds in these documents include (1) maintaining and managing HMAs at AMLs to ensure a thriving natural ecological balance between wild horse populations, wildlife, livestock, vegetation resources, and other resource values, and (2) enhancing and perpetuating special and unique characteristics that distinguish the herd.

1.4 Relationship to Laws, Regulations, and Other Plans

Statutes and Regulations

This action is governed by the WFRHBA of 1971 (Public Law (PL) 92-195 as amended) and Title 43 Code of Federal Regulations (CFR) part 4700. Gathering and disposal of the wild horses would be in accordance with PL 92-195 as amended by PL 94-579 (Federal Land Policy and Management Act (FLPMA)) and PL 95-514 (Public Rangelands Improvement Act (PRIA)). Included are:

- ❒ **43 CFR 4710.3-1 Herd management areas.**
  Herd management areas shall be established for the maintenance of wild horse and burro herds. In delineating each herd management area, the authorized officer shall consider the appropriate management level for the herd, the habitat requirements of the animals, the relationships with other uses of the public and adjacent private lands, and the constraints contained in 4710.4. The authorized officer shall prepare a herd management area plan, which may cover one or more herd management areas.
- ❒ **43 CFR 4710.4 Constraints on management.**
  Management of wild horses and burros shall be undertaken with limiting the animals' distribution to herd areas. Management shall be at the minimum feasible level necessary to attain the objectives identified in approved land use plans and herd management area plans.
- ❒ **43 CFR 4720.1 Removal of excess animals from public lands.**
  Upon examination of current information and a determination by the authorized officer that an excess of wild horses or burros exists, the authorized officer shall remove the excess animals immediately.
- ❒ **43 CFR 4740.1 Use of motor vehicles or aircraft.**
  (a) Motor vehicles and aircraft may be used by the authorized officer in all phases of the administration of the Act, except that no motor vehicle or aircraft, other than helicopters, shall be used for the purpose of herding or chasing wild horses or burros for capture or destruction. All such use shall be conducted in a humane manner.
  (b) Before using helicopters or motor vehicles in the management of wild horses or burros, the authorized officer shall conduct a public hearing in the area where such use is to be made.

1.5 Conformance with Rangeland Health Standards and Guidelines

As stated in 43 CFR 4180.2(b) - "Standards and guidelines must provide for conformance with the fundamentals of 43 CFR 4180.1." The Standards and Guidelines for Grazing Management for public lands have been reviewed by the Departmental Review Team who found that they comply with the requirements of the regulations. Gathering excess horses conforms to the standards and guides which were developed with full public participation and in consultation with Oregon/Washington's resource advisory councils and are in conformance with appropriate land use plans.

1.6 Decision to be Made

The authorized officer would determine whether to implement the proposed population control measures in order to achieve and maintain population size within the established AML and prevent the further deterioration of rangeland and riparian resources resulting from the current wild horse overpopulation. The authorized officer's decision would not set or adjust AML nor would it adjust livestock use, as these were set through previous decisions.

2.0 Proposed Action and Alternatives

2.1 Introduction

This section of the EA describes the Proposed Action and alternatives, including any that were considered but eliminated from detailed analysis. Five alternatives are considered in detail:

- Alternative 1: Proposed Action – Capture wild horses in order to remove approximately 250 excess wild horses, remove approximately 25 outside horses, apply PZP-22 fertility control vaccine to released mares, and establish a 60% male sex ratio.
- Alternative 2: – Capture wild horses in order to remove approximately 250 excess wild horses and remove approximately 25 outside horses (no fertility control or sex ratio adjustment).
- Alternative 3: Capture wild horses in order to remove approximately 250 excess wild horses, remove approximately 25 outside horses, and apply PZP-22 fertility control vaccine to released mares.
- Alternative 4: Capture wild horses in order to remove approximately 250 excess wild horses, remove approximately 25 outside horses, and establish a 60% male sex ratio.
- Alternative 5: No Action — Defer gather and removal.

The Proposed Action, Alternative 2, Alternative 3 and Alternative 4 were developed to respond to the identified resource issues and the Purpose and Need to differing degrees. The No Action Alternative would not achieve the identified Purpose and Need. However, it is analyzed in this EA to provide a basis for comparison with the other action alternatives, and to assess the effects of not conducting a gather at this time. The No Action Alternative is in violation of the WFRHBA which requires the BLM to immediately remove excess wild horses.

2.2 Description of Alternatives Considered in Detail

2.2.1 Management Actions Common to Alternatives 1-4

- ❑ The gather would begin about September 2011 and take about 20 days to complete. Several factors such as animal condition, herd health, weather conditions, or other considerations could result in adjustments in the schedule.
- ❑ Gather operations would be conducted in accordance with the Standard Operating Procedures (SOPs) described in the National Wild Horse and Burro Gather Contract (Appendix A). The primary gather (capture) methods would be the helicopter drive method with occasional helicopter assisted roping (from horseback).
- ❑ Trap sites and temporary holding facilities will be located in previously used sites or other disturbed areas whenever possible. Undisturbed areas identified as potential trap sites or holding facilities would be inventoried for cultural resources. If cultural resources are encountered, these locations would not be utilized unless they could be modified to avoid impacts to cultural resources.
- ❑ An Animal and Plant Inspection Service (APHIS) or other veterinarian may be on-site during the gather, as needed, to examine animals and make recommendations to BLM for care and treatment of wild horses.
- ❑ Decisions to humanely euthanize animals in field situations will be made in conformance with BLM policy (Washington Office Instruction Memorandum 2009-041). Current policy reference: http://www.blm.gov/wo/st/en/info/regulations/Instruction_Memos_and_Bulletins/national_instruction/2009/IM_2009-041.html
- ❑ Data including sex and age distribution, condition class information (using the Henneke rating system), color, size and other information may also be recorded, along with the disposition of that animal (removed or released).
- ❑ Hair samples would be collected on about 50-100 animals to assess the genetic diversity of the herd. Samples would also be collected during future gathers as needed to determine whether BLM's management is maintaining acceptable genetic diversity (avoiding inbreeding depression).
- ❑ Excess animals would be transported to the Burns BLM corral facility where they will be prepared (freeze-marked, vaccinated and de-wormed) for adoption, sale (with limitations) or long-term holding.
- ❑ Temporary closure of roads within the HMA during gather operations may be instituted as necessary to allow for safe and effective operations to proceed.

2.2.2 Alternative 1. Proposed Action

The Proposed Action would gather about 650 and remove approximately 275 excess wild horses from within and outside the Barren Valley Complex beginning about September 2011. Animals would be removed using a selective removal strategy. Selective removal criteria for the HMA include: (1) First Priority: Age Class – Four Years and Younger; (2) Second Priority: Age Class – Eleven to Nineteen Years (3) Third Priority: Age Class Five to Ten Years 4) Fourth Priority: Age Class Twenty Years and Older should not be removed from the HMA unless specific exceptions prevent them from being turned back to the range. Irrespective of their age class, all animals residing outside the HMA would be removed. Up to 559 of the captured wild horses would be released; of these, about 223 would be mares of which most would be treated with fertility control and about 336 would be studs (or geldings) as follows:

- ❒ Mares would be treated with a two-year Porcine Zona Pellucida (PZP-22) or similar vaccine and released back to the range. Fertility control treatment would be conducted in accordance with the approved standard operating and post-treatment monitoring procedures (SOPs, Appendix B). Mares would be selected to maintain a diverse age structure, herd characteristics and conformation (body type).
- ❒ Studs and geldings would be selected for release with the objective of establishing a 60% male sex ratio. Studs and geldings would be selected to maintain a diverse age structure, herd characteristics and body type (conformation).
- ❒ Post-gather, every effort would be made to return released horses to the same general area from which they were gathered.

2.2.3 Alternative 2: Removal Only

Alternative 2 would gather about 650 and remove approximately 275 excess wild horses from within and outside the Barren Valley Complex beginning about September 2011. Fertility control would not be applied and no changes to the herd's existing sex ratio would be made.

2.2.4 Alternative 3: Removal with Fertility Control

Alternative 3 would gather about 650 and remove approximately 275 excess wild horses from within and outside the Barren Valley Complex beginning about September 2011. Fertility control would be applied, but no changes to the herd's existing sex ratio would be made.

2.2.5 Alternative 4: Removal with Sex Ratio Adjustment

Alternative 4 would gather about 650 and remove approximately 275 excess wild horses from within and outside the Barren Valley Complex beginning about September 2011. The herd's existing sex ratio would be adjusted to establish a 60% male sex ratio. Fertility control would not be applied.

2.2.6 Alternative 5: No Action

Under the No Action Alternative, no gather would occur and no additional management actions would be undertaken to control the size of the wild horse population at this time.

2.3 Summary Comparison of Alternatives

Table 1: Summary Comparison of the Alternatives

Item	Alternative 1: Proposed Action	Alternative 2: Removal Only	Alternative 3: Removal and Fertility Control only	Alternative 4: Removal and Sex Ratio only	Alternative 5: No Action
Impacts to Wild Horses					
• Gather Number	650	650	650	650	0
• Removal Number	275	275	275	275	0
• Fertility Control - # Mares	200	0	200	0	0
• Post-Gather Sex Ratio	60/40	50/50	50/50	60/40	0
• Post-Gather Population Size by HMA	CLAT 198 SHHC 161 SS 90	CLAT 198 SHHC 161 SS 90	CLAT 198 SHHC 161 SS 90	CLAT 198 SHHC 161 SS 90	CLAT 255 SHHC 350 SS 90

2.4 Alternatives Considered but Dismissed from Detailed Analysis

2.4.1 Use of Bait and/or Water Trapping

It would not be timely, cost-effective or practical to use bait and/or water trapping as the primary gather method because the number of water sources on both private and public lands within and outside the HMA would make it almost impossible to restrict wild horse access to the selected water trap sites. When water sources become limited, accessibility to these water sources is extremely remote, thereby, becoming an unpractical and economically unfeasible method of gathering horses. As a result, this alternative was dismissed from detailed analysis.

2.4.2 Remove or Reduce Livestock within the HMA

This alternative was not brought forward for detailed analysis because it is outside the scope of the analysis and it is contrary to previous decisions which allocated forage for livestock use. Such an action would not be in conformance with the existing land use plan, would be contrary to the BLM's multiple-use mission as outlined in the 1976 Federal Land Policy and Management Act (FLPMA), and would also be inconsistent with the WFRHBA which directs the Secretary to immediately remove excess wild horses.

2.4.3 Gather the HMA to the AML Upper Limit

This alternative was dismissed from detailed study because AML would be exceeded the foaling season following the gather in 2011. This would result in the need to follow up with another gather within one year, and increased stress to individual wild horses and the herd and continuing resource damage due to wild horse overpopulation in the interim. Nor would this alternative be consistent with the WFRHBA, which upon determination excess wild horses are present, requires their immediate removal.

2.4.4 Fertility Control Treatment Only (No Removal)

Population modeling was completed to analyze the potential impacts associated with conducting gathers about every 2-3 years over the next 20 year period to treat captured mares with fertility control. Under this alternative, no excess wild horses would be removed. While the average population growth would be reduced for the next couple of years, AML would not be achieved and the damage to the range associated with wild horse overpopulation would continue. This alternative would not meet the Purpose and Need for the Action, and would be contrary to the WFRHBA, and was dismissed from further study.

3.0 Affected Environment

3.1 General Description of the Affected Environment

The Barren Valley Complex encompasses approximately 956,000 acres of public land within Malheur and Harney Counties, Oregon (Map 1). The complex is made up of three HMAs; Coyote Lake/Alvord-Tule Springs, Sheepshead/Heath Creek, and Sand Springs HMAs. The complex is partially located in the Owyhee uplands with the Owyhee River the east boundary of the Sand Springs HMA. Highway 78 is the boundary between the Sheepshead/Heath Creek and Sand Springs HMAs. The rest of this complex is located in the Alvord Desert and the eastern foothills of the Steens Mountains.

Precipitation in the Barren Valley Complex averages 6 inches in the Steens Mountain rainshadow to 12 inches on the top of the Sheepshead Mountains. Most of this precipitation comes during the winter and spring months in the form of snow, supplemented by localized thunderstorms during the summer months. The primary native vegetation varies throughout the allotment from salt desert vegetation communities to shrub-steppe communities. There is a variety of big sagebrush, low sagebrush, and perennial grasses.

3.2 Description of Affected Resources/Issues

Table 2 lists the elements of the human environment subject to requirements in statute, regulation, or executive order which must be considered.

Table 2: Supplemental Authorities and Other Elements

Supplemental Authorities	Present	Affected	Rationale
ACECs	**YES**	**NO**	Saddle Butte and Palomino Playa ACECs in Sand Springs HMA on the Vale District. Alvord Desert, Mickey Hot Springs, Mickey Basin, Serrano Point, and Borax Lake ACECs in Coyote Lake/Alvord-Tule Springs HMA on the Burns District. To prevent any impacts to ACECs, trap sites and temporary holding facilities would be located in previously disturbed areas. Use of trap sites or holding facilities outside existing areas of disturbance would not be located in areas with existing ACECs.
Air Quality	**YES**	**NO**	The planning area is outside a non-attainment area. Implementation of the Proposed Action would result in small and temporary areas of disturbance.
Cultural Resources	**YES**	**NO**	To prevent any impacts to cultural resources, trap sites and temporary holding facilities would be located in previously disturbed areas. Cultural resource surveys would be conducted prior to using trap sites or holding facilities outside existing areas of disturbance.
Environmental Justice	**NO**	**NO**	Not present.
Fish Habitat	**NO**	**NO**	Not present.
Floodplains	**NO**	**NO**	Not present.
Forest and Rangelands	**YES**	**YES**	Discussed below.
Human Safety	**YES**	**NO**	Implementing the road closures identified in Section 2.2 would eliminate the impacts to human safety created by the proposed action.
Migratory Birds	**NO**	**NO**	Not present.
Native American Religious Concerns	**NO**	**NO**	There are no known Native American Religious Concerns regarding this project.
Noxious Weeds	**YES**	**NO**	To prevent the risk for spread, any noxious weeds or non-native invasive weeds would be avoided when establishing and accessing trap sites and holding facilities.
Prime or Unique Farmlands	**NO**	**NO**	Not present.
Riparian-Wetland Zones	**YES**	**YES**	Discussed below.
T&E Species	**YES**	**YES**	Discussed below.
Water Quality	**YES**	**NO**	Locate trap sites and temporary holding facilities away from any riparian areas to avoid impacts to water quality.
Waste (Hazardous or Solid)	**NO**	**NO**	Not present.
Wild and Scenic Rivers	**NO**	**NO**	Not present.
Wilderness and Wilderness Study Area	**YES**	**NO**	Wilderness Study Areas of: Palomino Hills (3-114) and Saddle Butte (3-111) are located within the Vale District; Wildcat Canyon (2-72C) and Sheepshead Mountain (2-72D) are located within the Vale and shared with the Burns District are located within the HMA. To prevent any impacts to WSA values, trap sites and temporary holding facilities would be located in previously disturbed areas. Use of trap sites or holding facilities outside existing areas of disturbance would not be located in areas with existing WSA values.

In addition to the critical elements listed in Table 2, the following resources may be affected by the Action Alternatives and/or the No Action Alternative. The existing situation (affected environment) relative to these resources is described below.

3.2.1 Wild Horses

Coyote Lake/Alvord-Tule Springs HMA

The Coyote Lake/Alvord-Tule Springs HMA is comprised of portions of four allotments in both Vale and Burns District BLM. The topography of the HMA ranges from relatively flat to mountainous. Elevation varies from approximately 3,900 to 6,100 feet, with the southern end of the Sheepshead Mountains being the highest prominent landmark.

The area's designation as a herd management area was analyzed in the SEORMP/FEIS (2001). AML is established at a population range of 198 - 390 wild horses. Forage is allocated for 4680 animal unit months (AUMs). Inventory data show the majority of wild horses historically concentrating on Red Mountain, Tule Springs, and Mickey Basin throughout the spring, summer, and fall as water sources and forage become scarce. During most winters, horses tend to disperse across the lower elevations in the HMA as water becomes available in potholes and playas.

The current estimated population of 250 wild horses in the Coyote Lake/Alvord-Tule Springs HMA is based on a direct count aerial population survey completed in April 2010. Calculation of population growth has been difficult to determine by individual HMA as horses continually move into adjacent HMAs. The current population is approximately 50 horses over the AML lower limit.

In the early 1970's, wild horses within the Coyote Lake portion of the HMA were very varied in color while the Alvord-Tule Springs portion of the HMA was dominated by bay, black, brown, sorrel, palomino, and buckskin. Adult horses in the HMA weigh an average of 950 to 1150 pounds and stand between 14.3 and 15.3 hands, with some stallions being slightly larger. The horses exhibit saddle stock conformation with quarter horse and thoroughbred influence.

Baseline genetic diversity samples were taken in 2001. These samples indicate that genetic variability within the Coyote Lake/Alvord-Tule Springs HMA is moderate to good. The herd appears to be of mixed origins from light racing and riding breeds which includes the thoroughbred and quarter horse. In comparison with other Oregon herds, the Coyote Lake/Alvord-Tule Springs herd shows closest resemblance to the Jackies Butte and Paisley herds.

The last removal of excess wild horses from the Coyote Lake/Alvord-Tule Springs HMA was completed in November 2008 when 393 horses were gathered and 244 were removed. Seventy-four mares were fertility control treated and released with 70 stallions/geldings for a post-removal 50/50 % male/female sex ratio.

Sheepshead/Heath Creek HMA

The Sheepshead/Heath Creek HMA is comprised of portions of two allotments in both Vale and Burns District BLM. The topography of the HMA ranges from relatively flat to mountainous. Elevation varies from approximately 3,900 to 6,300 feet, with the northern end of the Sheepshead Mountains being the highest prominent landmark. Approximately 20% of this HMA burned in the Sheepshead fire in 2001. There have been several smaller fires within this area from the 1980's to present. The location of the Sheepshead burn is where most of the horses are currently congregated within the HMA.

The area's designation as a herd management area was analyzed in the AMURMP/FEIS (2004). AML is established at a population range of 161-302 wild horses. Forage is allocated for 3624 AUMs. Inventory data show the majority of wild horses historically concentrating on the north end of the Sheepshead Mountains, Bone Springs Canyon, and Wildcat Canyon yearlong.

The current estimated population of 350 wild horses in the Sheepshead/Heath Creek HMA is based on a direct count aerial population survey completed in April 2010. Calculation of population growth has been difficult to determine by individual HMA as horses continually move into adjacent HMAs, but the overall population growth in the Barren Valley Complex has been over 20% since the previous gather. The increase in numbers in Sheepshead/Heath Creek HMA indicates there has most likely been movement from adjacent HMAs. The current population in this HMA is approximately 190 horses over the AML lower limit.

In the early 1970's, wild horses within the Sheepshead portion of the HMA were very varied in color while the Heath Creek portion of the HMA was dominated by dun, bay, black, brown, sorrel, and an occasional paint. Adult horses in the HMA weigh an average of 950 to 1150 pounds and stand between 14.3 and 15.3 hands, with some stallions being slightly larger. The horses exhibit saddle stock conformation with quarter horse and thoroughbred influence.

Baseline genetic diversity samples were taken in 2002. These samples indicate that genetic variability within the Sheepshead/Heath Creek HMA is low. The herd appears to be of mixed origins from North American gaited breeds and occasional draft horse influence. In comparison with other Oregon herds, this HMA shows closest resemblance to the Paisley HMA.

The last removal of excess wild horses from the Sheepshead/Heath Creek HMA was completed in November 2008 when 233 horses were gathered and 145 were removed. Forty-six mares were fertility control treated and released with 43 stallions/geldings for a post-removal 40/60% male/female sex ratio.

Since the Barren Valley Complex was identified as individual HMAs in the 1970's, management and gathers have occurred independently and cooperatively. Therefore, the table below reflects the gather history for all of the HMAs in the Barren Valley Complex except for Sand Springs HMA.

Table 3: Coyote Lake/Alvord-Tule Springs and Sheepshead/Heath Creek Gather History

HMA	Year	Captured	Removed	Released	Died/Euthanized
Coyote Lake/Alvord-Tule Springs	2008	393	244	184	4
Sheepshead/Heath Creek	2008	212	145	84	1
Coyote Lake/Alvord-Tule Springs	2005	367	367		
Sheepshead/Heath Creek	2002	320	257	63	
Coyote Lake/Alvord-Tule Springs	2001	303	303

Alvord/Barren Valley/Sheepshead/Tule Springs	1981	338	336	0	2
Barren Valley/Sheepshead/Alvord	1979	518	510	5	3
Sheepheads/Coyote Lake	1977	599	598	0	1
Barren Valley/Sheepshead/Alvord	1976	8	8	0	0
Barren Valley/Sheepshead/Alvord	1975	20	20	0	0
Barren Valley/Sheepshead/Alvord	1974	38	35	0	3

Sand Springs HMA

The Sand Springs HMA is comprised of portions of two allotments in the Vale District. The topography of the HMA ranges from relatively flat to river canyon country. Elevation varies from approximately 3,900 to 4,500 feet, with Saddle Butte being the highest prominent landmark just outside the north boundary of the HMA. Approximately 35% of this HMA burned in the Happy Valley fire in 2006. There have been several smaller fires within this area from the 1980's to present. The location of the Happy Valley fire is where the perennial upland water sources are located in the HMA, thereby being in the heart of summer range and habitat.

The area's designation as a herd management area was analyzed in the SEORMP/FEIS (2001). AML is established at a population range of 100-200 wild horses. Forage is allocated for 2400 AUMs. Inventory data show the majority of wild horses historically concentrating on the rims above the Owyhee River during the winter and around the few perennial springs during the spring, summer, and fall.

The current estimated population of 90 wild horses in the Sand Springs HMA is based on a direct count aerial population survey completed in April 2010. Calculation of population growth has been difficult to determine by individual HMA as horses continually move into adjacent HMAs, but the increase in numbers in this HMA indicates there has most likely been movement from adjacent HMAs. The current population in this HMA is approximately 10 horses under the AML lower limit.

In the early 1970's, wild horses within the Sand Springs HMA were very predominantly pinto and buckskin colors. Adult horses in the HMA weigh an average of 950 to 1050 pounds and stand between 14.2 and 15.2 hands, with some stallions being slightly larger. The horses exhibit saddle stock conformation with quarter horse and thoroughbred influence.

Baseline genetic diversity samples have not been analyzed for this herd.

The last removal of excess wild horses from the Sand Springs HMA was completed in September 2006 when 130 horses were gathered and 115 were removed in an emergency gather following a large wildfire.

Table 4: Sand Springs Gather History

HMA	Year	Captured	Removed	Released	Died/Euthanized
Sand Springs	2006	130	115	15	5
Sand Springs	2005	280	220	60	2
Sand Springs	2000	194	138	56	1
Sand Springs	1992	189	189		
Sand Springs	1988	208	208		
Sand Springs	1985	327	325	0	2
Sand Springs	1981	350	246	0	4
Sand Springs	1977	280	277	0	3

Most of the wild horses observed in the Barren Valley Complex in 2010 were a Body Condition Score of 4-6 using the Henneke Body Condition Chart.

3.2.2 Grazing Management

Coyote Lake/Alvord-Tule Springs HMA

The Coyote Lake portion of the HMA is located within the Coyote Lake Allotment and part of the Whitehorse Butte Allotment in the Vale Distrit. Coyote Lake has two livestock operators. One operator is authorized to utilize 344 active AUMs from November 16 to February 14 and the other operator is authorized to utilize 3014 active AUMs and 1945 exchange of use AUMs from October 1 to January 31. Livestock grazing reductions

have been made on a voluntary basis by past owners of the White Horse Ranch in the Red Mountain North pasture due to lack of water and impacts on Willow Creek.

The BLM allocated forage for livestock use in the SEORMP/ROD (2002,p. E-181). The allocation was carried forward from the Southern Malheur Rangeland Program Summary Update (December 1986). The allocation will be revisited during activity planning associated with evaluation and assessment within Barren Valley Geographic Management Area as described in the SEORMP.

The Alvord-Tule Springs portion of the HMA is located within the Alvord Allotment in the Burns District. There are four pastures within the allotment. Three of the pastures are authorized as spring/summer use and one pasture is authorized as winter use. There is one livestock operator authorized to graze a total of 7,355 AUMs of annually from December 1 to April 15 on the winter pasture and from April 16 to June 30 on the spring pastures.

Forage for livestock use was most recently allocated by the BLM in the 2005 AMURMP/ROD. The allocation will be revisited during activity planning associated with evaluation and assessment within the Alvord Allotment as described in the Andrews RMP.

Table 5 summarizes information about livestock grazing and its relationship to wild horse management within the Coyote Lake/Alvord-Tule Springs HMA.

Table 5: Livestock Use Information

Allotment	Total Allotment Acres	% of Allotment in HMA	Number of Permittees	Number of Authorized Livestock	Authorized Season of Use	Authorized Livestock AUMs in Allotment	Average Actual Livestock Use (AUMs) (Past 5 years)
Coyote Lake	162,858 PD 15,500 Pvt 80 State	100%	2	Cattle	10/01-02/14	3,358	414 minimum 1,737 average 4,257 maximum
Whitehorse Butte	124,821 PD 14,544 Pvt 166 State	19%	1	Cattle	03/16-08/31	9,287	5152 average 3130 minimum 8089 maximum
Alvord	223,895 PD 5,600 Pvt	38%	1	700 Cattle 1254 cattle	4/16 – 6/30 12/01-4/15	7,355	1660 minimum 6035 average 8859 maximum

Sheepshead/Heath Creek HMA

The Sheepshead portion of the HMA is located within the Sheephead Allotment in the Vale District. There is one operator authorized to graze cattle annually, and who is authorized to utilize 3,949 active Animal Unit Months (AUMs) of forage within the allotment each year between March 01 and February 28. Currently there is no Allotment Management Plan (AMP) for the Sheephead Allotment. There is also no established grazing system within the Sheephead Allotment; however the permittee rotates his cattle around four unfenced use areas which are Palomino Hills, East and West Ryegrass and Sheephead.

The BLM allocated forage for livestock use in the SEORMP/ROD (2002, p. E-178). The allocation was carried forward from the Southern Malheur Rangeland Program Summary Update (December 1986). The allocation will be revisited during activity planning associated with evaluation and assessment within Barren Valley Geographic Management Area as described in the SEORMP.

The Heath Creek portion of the HMA is located within the Pollock Allotment in the Burns District. There are seven pastures within the allotment. Six of the pastures are authorized as spring/summer use and one pasture is authorized as winter use. There is one livestock operator authorized to graze a total of 4107 AUMs annually between November 15 to March 31 on the winter pasture and from April 1 to September 15 on the spring/summer pastures.

Table 6 summarizes information about livestock grazing and its relationship to wild horse management within the Sheepshead/Heath Creek HMA.

Table 6: Livestock Use Information

Allotment	Total Allotment Acres	% of Allotment in HMA	Number of Permittees	Number of Authorized Livestock	Authorized Season of Use	Authorized Livestock AUMs in Allotment	Average Actual Livestock Use (AUMs) (Past 5 years)
Sheepshead	152,037 PD 1,102 Pvt 602 State	100%	1	597 Cattle	03/01-02/28	3,949	3,966 minimum 4,057 average 4,233 maximum
Pollock	76,758 PD 4,895 Pvt 5,561 State	32%	1	520 Cattle 530 cattle	4/01 – 9/15 11/15-3/31	4107	1431 minimum 4305 average 4783 maximum

Sand Springs HMA

The Sand Springs HMA is located primarily within the Saddle Butte Allotment in the Vale District. There are a total of seven livestock operators authorized to graze cattle annually. The operators are authorized to utilize 6,314 Animal Unit Months (AUMs) of forage within the allotment each year between November 1 and March 31. An AUM is the amount of forage needed to sustain one cow, five sheep, or five goats for a month. The allotment is comprised of one pasture which is grazed by livestock. The Saddle Butte Allotment Management Plan (AMP) acknowledged that no formal grazing system was developed given that the allotment was to be grazed during the winter. Within the Saddle Butte Allotment the approximate growth period for the key forage species, bottlebrush squirreltail *(Elymus elymoides)*, is March 25 through August 1. Winter grazing use in the Saddle Butte Allotment is based on that year's forage production.

The BLM allocated forage for livestock use in the SEORMP/ROD (2002, p. E-208). The allocation was carried forward from the Southern Malheur Rangeland Program Summary Update (December 1986). The allocation will be revisited during activity planning associated with evaluation and assessment within Saddle Butte Geographic Management Area as described in the SEORMP.

Table 7 summarizes information about livestock grazing in Saddle Butte Allotment and its relationship to wild horse management within the Sand Springs HMA.

Table 7: Livestock Use Information

Allotment	Total Allotment Acres	% of Allotment in HMA	Number of Permittees	Number of Authorized Livestock	Authorized Season of Use	Authorized Livestock AUMs in Allotment	Average Actual Livestock Use (AUMs) (Past 5 years)
Saddle Butte	175,841 PD 9,172 Pvt 623 State	100%	7	1,714 Cattle	11/1 – 3/31	6,314	1,999 minimum 4,081 average 5,971 maximum

3.2.3 Wildlife

The project area includes habitat for approximately 300 wildlife species. Many of these species use the area for part of the year and/or as connective habitat while traveling to more productive ground.

Big Game: Pronghorn Antelope are widely distributed across the project area and represent the primary big game species in this area. Mule deer use this area throughout the year, but are only found in large numbers during the winter. During October through May this area is particularly important as Mule deer winter range habitat. Elk also use this area in the winter, but are less frequent than pronghorn antelope and mule deer. California Bighorn sheep are common on the Sheepshead Mountains, Red Mountain, and around Tule Springs, but only use Coyote Lake in winter.

Raptors: A variety of Raptor species use the project area at various times during the year. Most Raptors species migrate through and are only in the area for a short time. These include: the bald and golden eagle, Swainson's, Ferruginous, red- tailed and sharp shinned hawk, prairie and peregrine falcon, northern harrier, American Kestrel, and Western burrowing owl.

Other important game species known to occur in the HMA include chukar and Hungarian partridge, mourning doves, and sage grouse.

The area lacks perennial water and habitat for native species of fish.

3.2.4 Threatened and Endangered/Special Status Species

No threatened and/or endangered animal species are known or suspected to occur within the Barren Valley Complex. Special status wildlife species likely to occur within the project area include kit fox, spotted bat, pygmy rabbit, peregrine falcon, and sage grouse.

Greater sage grouse: The greater sage grouse is currently a species that is considered "warranted for listing under the Endangered Species Act of 1973. A small number of sage grouse use this area, but wildfire has reduced the amount of sage brush and diminished the habitat. Approximately half of the Barren Valley HMA is considered category 2 sage grouse habitat. The northern quarter of the unit is category 1. The management goals for category 2 sage grouse habitat are: avoid development within these areas, or if impacts are unavoidable, maintain the current habitat quantity or quality and provide a net benefit to sage grouse habitat. Category 1 habitat is priority habitat for sage grouse. Actions within category 1 habitat should not diminish or reduce the quality of habitat for sage grouse.

Information on the remaining special status species is limited, but the likelihood of additional special status species using this area for a significant portion of their life history requirements is low.

Special Status Plant Species:

In February 2008 a new interagency special status species list for Oregon/Washington BLM and Region 6 of the USFS was developed (BLM 2008). The interagency list is an attempt to coordinate management for rare species across land ownership boundaries. This new and most current list used new criteria to determine if species are sensitive and eliminated the categories of Bureau Assessment and Bureau Tracking Species. As a result, some previously listed species have come off the list and some species' status has changed from sensitive to strategic. There are now three categories of special status species for Oregon/Washington BLM and Region 6 of the USFS: Federally listed species under the ESA, and Sensitive species or Strategic species as designated by the State Director or the Regional Forester.

A number of previously known special status plants in the Barren Valley complex are no longer special status. This change in status could be due to a number of factors such as the new criteria in determining if species are sensitive or expansion of a species range as a result of increased inventory and survey. For this reason only those plants presently designated as Bureau Sensitive or Bureau Strategic will be addressed within this section.

Within the Barren Valley Complex nine different special status species occur: Davis' peppergrass (*Lepidium davisii*), Desert chaenactis (*Chaenactis xantiana*), Transmontane sand-verbena (*Abronia turbinata*), Wheeler's skeleton-weed (*Chaetadelpah wheeleri*), Lyrate malacothrix (*Malacothrix sonchoides*), Salt heliotrope (*Heliotropium curassavicum*), Iodine bush (*Allenrolfea occidentalis*) and Desert needlegrass (*Achnatherum speciosum*). Aside from Davis' peppergrass, abundance of all other species occurrences is low with isolated infrequent pockets throughout the complex. Wild horses do not pose a known threat to the aforementioned species aside from Davis' peppergrass.

Davis' peppergrass (*Lepidium davisii*), is a Bureau Sensitive specie with known occurrences in five playas within the Coyote Lake/Alvord – Tule Springs HMA and seven playas within Sand Springs HMA. Recent and past monitoring reveals heavy horse use on the playas. The use generally occurs during times when the playas are wet and being used as a water source for the horses. This continues through most of the summer, causing extensive soil compaction and heavy disturbance. In Oregon wild horse impact is the primary threat to this species.

3.2.5 Vegetation

Shrub steppe vegetation communities in the area result from cold winters and hot dry summers. Historically, the project area supported a wide variety of sagebrush/perennial grassland cover types. Disturbance factors that have occurred within the complex include historic domestic livestock grazing use, wild horse grazing use, wildfire and invasive plants. Outside of seedings and cheatgrass, this vast area consists of a sagebrush (*Artemisia*) overstory with an understory dominated by perrenial bunchgrass. Dominant species of shrub and bunchgrass include: Wyoming big sagebrush (*Artemisia tridentata* ssp. *wyomingensis*), mountain big sagebrush (*Artemisia tridentata* ssp. *vaseyana*), low sagebrush (*Artemisia arbuscula*), shadscale (*Atriplex confertiflora*), spiny hopsage (*Grayia spinosa*), Sandberg bluegrass (*Poa sandbergii*), Cusick's bluegrass (*Poa cusickii*), bluebunch wheatgrass (*Pseudorogneria spictata*), Thurber's needlegrass (*Achnatherum thurberiana*), Idaho fescue (*Festuca idahoensis*) and Indian ricegras (*Achnatherum hymenoides*). Riparian habitats are very infrequent throughout the complex. Riparian vegetation consists of but is not limited to the following: Beardless wildrye (*Leymus triticoides*), Coyote willow (*salix exigua*), yellow willow (*Salix lutea*), Nebraska sedge (*Carex nebraskensis*), *Carex* sp., spikerush (*Eleocharis* sp.), Baltic rush (*Juncus balticus*), tufted hairgrass (*Deschampsia caespitosa*), alpine timothy (*Phleum alpinum*), Leiberg's bluegrass (*Poa leibergii*), hardstem bulrush (*Schoenoplectus acutus*), and cattail (*Typha* sp.).

Portions of the complex are infested with a conglomerate of mostly annual weeds or weedy species. Perennial pepperweed (*Lepidium latifolium*), whitetop (*Lepidium spp.),* Russian knapweed (*Acroptilon repens*), halogeton (*Halogeton glomeratus*) and saltcedar (*Tamorix ramosissima*) are common in the Upper and Lower Willow Creek Waterholes areas (Little Coyote Playa). With the exception of saltcedar, these species as well as Scotch (*Onapordum acanthium*) and Canada thistle (*Circium arvense*), occur as small, isolated patches within other portions of the area.

3.2.6 Soils

The soils found in the Barren Valley Complex were surveyed and described in Oregon's Long Range Requirements for Water 1969, Appendix I-11, Owyhee Drainage Basin and Appendix I-12. They are mainly a

combination of Unit 75 and 77 soils on slopes varying from three to twelve percent and Unit 30 and 55 soils on slopes varying from zero to twelve percent. The area also contains smaller amount of Units 57, 76, and 99.

Unit 30 soils are deep, poorly drained soils formed in fine-textured alluvium on flat basins and old playa bottoms. The native vegetation consists mostly of western wheatgrass, silver sagebrush, big sagebrush, and rabbitbrush.

Unit 55 soils are shallow, loamy, well drained soils with cemented pans. These soils occur on very extensive to moderately steep old fans and high terrace remnants. Native vegetation consists mostly of big sagebrush, low sagebrush, rabbitbrush, budsage, Atriplex spp., needlegrass, squirreltail grass, and Sandberg bluegrass.

Unit 57 soils are deep, well drained soils derived from loamy materials on old fans. Sloes are dominantly nearly level to gently sloping. Native vegetation consists mostly of big sagebrush, low sagebrush, rabbitbrush, budsage, Atriplex spp., needlegrass, and squirreltail grass.

Unit 75 soils are loamy, shallow, very stony, well drained soils over basalt, rhyolite, or welded tuff. Unit 75 soils occur on gently undulating to rolling lava plateaus with some very steep faulted and dissected terrain. The soil profile consists of very stony silt loam, stony loam, and stony silt loam over bedrock at 15+ inches.

Unit 76 soils are shallow, clayey, very stony, well drained soils over basalt, rhyolite, or welded tuff. They occur on gently undulating to rolling lava plateaus and some very steep faulted and dissected terrain. The soil profile consists of very stony, silt loam, stony silty clay, to stony and channery, heavy, silty clay loams over fractured bedrock at 18+ inches.

Unit 77 soils are very shallow, very stony, rocky, well-drained soils over basalt, rhyolite, or welded tuff. These soils occur on gently undulating to rolling lava plateaus. Native vegetation consists mostly of big sagebrush, low sagebrush, and Sandberg bluegrass.

Unit 99 is a miscellaneous land unit consisting of recent lava flows. These flows are generally on low slopes, but do have extremely irregular, rough surfaces. There do tend to be small pockets of soil development on which there is some vegetation.

3.2.7 Riparian Areas and Water Resources

In the Coyote Lakes portion of the HMA, Willow Creek is the only perennial riparian area. Willow Creek is on the State of Oregon's 303(d) list which indicates that the stream is unable to meet water quality standards. Oregon Department of Environmental Quality (ODEQ) has initiated a Total Maximum Daily Load study on Willow Creek (Willow Creek Total Maximum Daily Load, ODEQ, March 1999). This study identifies wild horse grazing in the riparian area as one of the factors contributing to the stream's degraded condition.

In the Alvord-Tule Springs portion of the HMA, the only perennial water sources are springs in Mickey Basin, Mickey Hot Springs, and Tule Springs. Wells provide some extension of range during the winter. Season long grazing near perennial springs, (Tule Springs, Buckbrush Springs, Big Sand Gap Springs, Little Sand Gap Springs), and Calderwood Desert Well, becomes a resource concern as horse numbers continue to increase. Table Mountain pasture has historically perennial springs and water holes fed from Wildcat Creek which are currently dry. There are a few scattered playas and seeps throughout the rest of the HMA that provide limited riparian habitat.

Riparian areas in the Sheepshead/Heath Creek HMA are associated with a few perennial springs, Heath Creek, Wildcat Canyon, and bone Canyon. The entire riparian habitat in this HMA is associated with the higher elevations along the ridges associated with the Sheepshead Mountains. Most of the limited water sources in the lower elevations of this HMA are associated with reservoirs.

Riparian vegetation in the Sand Springs HMA is extremely limited, existing primarily at a few scattered springs and reservoirs. Most of the riparian areas are related to several perennial springs and seeps along the eastern edge of the HMA above the Owyhee River Rim. There are also several natural water gaps on the Owyhee River that wild horses rarely use.

While not extensive, riparian zones are an important resource for wildlife, wild horses, and livestock. Because of the demands on riparian areas, management considerations have focused on protecting these areas. Maintaining AML of wild horse herds is important to keeping utilization at acceptable levels and preserving riparian habitat.

4.0 Environmental Consequences

4.1 Introduction

This section of the EA documents the potential environmental impacts which would be expected with implementation of the Action Alternatives (Alternatives 1-4) and/or the No Action Alternative. These include the direct impacts (those that result from the management actions) and indirect impacts (those that exist once the management action has occurred).

4.2 Predicted Effects of Alternatives

The direct and indirect impacts to these resources which would be expected to result with implementation of the Action Alternatives or No Action Alternative are discussed in detail below.

4.2.1 Wild Horses

Results of Win Equus Population Modeling

The Alternatives were modeled using Version 3.2 of the Win Equus population model (Jenkins, 2000). The purpose of the modeling was to analyze and compare the effects of the Action Alternatives on population size, average population growth rate, and average removal number. Another objective of the modeling was to identify if any of the alternatives "crash" the population or cause extremely low population numbers or growth rates.

Minimum population levels and growth rates were found to be within reasonable levels and adverse impacts to the population are not likely. There was not a significant difference in the Action Alternatives for the number average number of horses removed over the next 11 years. See Appendix C for additional detail.

Impacts Common to Action Alternatives (1-4)

Over the past 35 years, various impacts to wild horses as a result of gather activities have been observed. Under the Proposed Action, impacts to wild horses would be both direct and indirect, occurring to both individual horses and the population as a whole.

The BLM has been conducting wild horse gathers since the mid-1970s. During this time, methods and procedures have been identified and refined to minimize stress and impacts to wild horses during gather implementation. The SOPs (Appendix A) would be implemented to ensure a safe and humane gather occurs

and would minimize potential stress and injury to wild horses. In addition to implementation of the SOPs, BLM would temporarily close roads in the HMA where gather operations were occurring to assist in ensuring the safety of the public, BLM contractors, BLM personnel, and wild horses.

In any given gather, gather-related mortality averages about one half of one percent (0.5%), which is very low when handling wild animals. Approximately another six-tenths of one percent (0.6%) of the captured animals could be humanely euthanized due to pre-existing conditions and in accordance with BLM policy (IM-2009-041). These data affirm that the use of helicopters and motorized vehicles has proven to be a safe, humane, effective, and practical means for the gather and removal of excess wild horses (and burros) from the public lands. The BLM also avoids gathering wild horses by helicopter during the 6 weeks prior to and following the peak foaling season (i.e., March 1 through June 30).

Individual, direct impacts to wild horses include the handling stress associated with the roundup, capture, sorting, handling, and transportation of the animals. The intensity of these impacts varies by individual, and is indicated by behaviors ranging from nervous agitation to physical distress. When being herded to trap site corrals by the helicopter, injuries sustained by wild horses may include bruises, scrapes, or cuts to feet, legs, face, or body from rocks, brush or tree limbs. Rarely, wild horses may encounter barbed wire fences and may receive wire cuts. These injuries are very rarely fatal and are treated on-site until a veterinarian can examine the animal and determine if additional treatment is indicated.

Other injuries may occur after a horse has been captured and is either within the trap site corral, the temporary holding corral, during transport between facilities, or during sorting and handling. Occasionally, horses may sustain a spinal injury or a fractured limb but based on prior gather statistics, serious injuries requiring humane euthanasia occur in less than 1 horse per every 100 captured.

To minimize the potential for injuries from fighting, the animals are transported from the trap site to the temporary (or short-term) holding facility where they are sorted as quickly and safely as possible, then moved into large holding pens where they are provided with hay and water.

Indirect individual impacts are those which occur to individual wild horses after the initial event. These may include miscarriages in mares, increased social displacement, and conflict in studs. These impacts, like direct individual impacts, are known to occur intermittently during wild horse gather operations. An example of an indirect individual impact would be the brief skirmishes between older studs which ends when one stud retreats. Injuries typically involve a bite or kick with bruises which do not break the skin. Like direct individual impacts, the frequency of these impacts varies with the population and the individual. Observations following capture indicate the rate of miscarriage varies, but can occur in about 1 to 5% of the captured mares, particularly if the mares are in very thin body condition or in poor health.

Gathering the wild horses during the Fall/Winter reduces risk of heat stress, although this can occur during any gather, especially in older or weaker animals. Adherence to the SOPs as well and techniques used by the gather contractor help minimize the risks of heat stress. Heat stress does not occur often, but if it does, death can result. Most temperature related issues during a gather can be mitigated by adjusting daily gather times to avoid the extreme hot or cold periods of the day.

A few foals may be orphaned during a gather. This can occur if the mare rejects the foal, the foal becomes separated from its mother and cannot be matched up following sorting, the mare dies or must be humanely euthanized during the gather, the foal is ill or weak and needs immediate care that requires removal from the mother, or the mother does not produce enough milk to support the foal. On occasion, foals are gathered that

were previously orphaned on the range (prior to the gather) because the mother rejected it or died. These foals are usually in poor, unthrifty condition. Every effort is made to provide appropriate care to orphan foals. Veterinarians may administer electrolyte solutions or orphan foals may be fed milk replacer as needed to support their nutritional needs. Orphan foals may be placed in a foster home in order to receive additional care. Despite these efforts, some orphan foals may die or be humanely euthanized as an act of mercy if the prognosis for survival is very poor.

Wild horses not captured may be temporarily disturbed and moved into another area during the gather operation. With the exception of changes to herd demographics from removals, direct population impacts have proven to be temporary in nature with most, if not all, impacts disappearing within hours to several days of release. No observable effects associated with these impacts would be expected within one month of release, except for a heightened awareness of human presence.

It is not expected that genetic health would be negatively impacted by the Proposed Action. The AML range in the Barren Valley Complex of 559-892 should provide for acceptable genetic diversity.

By maintaining wild horse population size within the AML within the Sheepshead/Heath Creek HMA, there would be a lower density of wild horses across all of the HMAs within the complex. This results in reducing competition for resources and allowing wild horses to utilize their preferred habitat. Maintaining population size within the established AMLs would be expected to improve forage quantity and quality and promote healthy, self-sustaining populations of wild horses in a thriving natural ecological balance and multiple use relationship on the public lands in the area. Deterioration of the range associated with wild horse overpopulation would be avoided. Managing wild horse populations in balance with the available habitat and other multiple uses would lessen the potential for individual animals or the herd to be affected by drought, and would avoid or minimize the need for emergency gathers, which would reduce stress to the animals and increase the success of these herds over the long-term.

Transport, Short Term Holding, and Adoption (or Sale) Preparation

About 275 excess horses would be removed. Animals would be transported from the capture/temporary holding corrals to the designated BLM short-term holding corral facility(s) according to SOPs (Appendix A). During transport, potential impacts to individual horses can include stress, as well as slipping, falling, kicking, biting, or being stepped on by another animal. Unless wild horses are in extremely poor condition, it is rare for an animal to be seriously injured or die during transport.

Upon arrival at the short term holding facility, most wild horses begin to eat and drink immediately and adjust rapidly to their new situation. Recently captured wild horses, generally mares, in very thin condition may have difficulty transitioning to feed. Some of these animals are in such poor condition that it is unlikely they would have survived if left on the range. Similarly, some mares may lose their pregnancies. Every effort is taken to help the mare make a quiet, low stress transition to captivity and domestic feed to minimize the risk of miscarriage or death.

After recently captured wild horses have transitioned to their new environment, they are prepared for adoption or sale. During the preparation process, potential impacts to wild horses are similar to those that can occur during handling and transportation. Serious injuries and deaths from injuries during the preparation process are rare, but can occur.

At short-term corral facilities, a minimum of 700 square feet is provided per animal. Mortality at short-term holding facilities averages approximately 5% per year (GAO-09-77, page 51), and includes animals euthanized

due to a pre-existing condition; animals in extremely poor condition; animals that are injured and would not recover; animals which are unable to transition to feed; and animals which are seriously injured or accidentally die during sorting, handling, or preparation.

From there, they would be made available for adoption or sale to qualified individuals or to long-term holding (grassland) pastures.

Adoption or Sale with Limitations, and Long Term Holding
Other indirect impacts include transportation to adoptions, sales, or long-term pastures (LTP). Adoptions are conducted in accordance with 43 CFR 5750. Sales of wild horses are conducted in accordance with Bureau policy. The BLM has maintained long-term pastures (LTP) in the Midwest for over 20 years. Potential impacts to wild horses from transport to adoption, sale or LTP are similar to those previously described.

LTPs are designed to provide excess wild horses with humane, life-long care in a natural setting off the public rangelands. Handling by humans is minimized to the extent possible although regular on-the-ground observation and weekly counts of the wild horses to ascertain their numbers, well-being, and safety are conducted.

Impacts of Alternative 1 (Proposed Action)
PZP application would be done according to SOPs (Appendix B). When injected, PZP (antigen) causes the mare's immune system to produce antibodies and these antibodies bind to the mare's eggs, and effectively block sperm binding and fertilization (Zoo Montana, 2000). PZP is relatively inexpensive, meets BLM requirements for safety to mares and environment, and can easily be administered in the field. In addition, among mares, PZP contraception appears to be completely reversible.

The highest success for fertility control has been obtained when applied during the timeframe of November through February. This gather would require PZP application outside the window for highest success. Below is the efficacy for the application of the two-year PZP vaccine:

		Year 1	Year 2	Year 3	Year 4
Summer Application	Normal	80%	65%	50%	
Winter Application	Normal	94%	82%	68%	

One-time application at the capture site would not affect normal development of the fetus, hormone health of the mare or behavioral responses to stallions, should the mare already be pregnant when vaccinated (Kirkpatrick, 1995). The vaccine has also proven to have no apparent effect on pregnancies in progress, the health of offspring, or the behavior of treated mares (Turner, 1997). Mares would foal normally in 2012 (Year 1).

Mares receiving the vaccine would experience slightly increased stress levels associated with handling while being vaccinated and freeze-marked. Serious injection site reactions associated with fertility control treatments are rare in treated mares. Any direct impacts associated with fertility control, such as swelling or local reactions at the injection site, would be minor in nature and of short duration. Most mares recover quickly once released back to the HMA, and none are expected to have long term consequences from the fertility control injections.

Under Alternative 1, some captured wild horses would be released back to the range to achieve a post-gather sex ratio of 60% studs or geldings and 40% mares. Under this alternative, band size would be expected to decrease, competition for mares would be expected to increase, recruitment age for reproduction among mares

would be expected to decline, and size and number of bachelor bands would be expected to increase. These effects would be slight, as the proposed sex ratio is not an extreme departure from normal sex ratio ranges. Modification of sex ratios for a post-gather population favoring studs or geldings would further reduce growth rates in combination with fertility control.

Impacts of Alternative 2 (Removal Only)
Implementation of Alternative 2 would result in capturing fewer wild horses than would be captured in Alternative 1. Alternative 2 would not involve fertility control; mares would not undergo the additional stress of receiving fertility control injections or freeze-marking and would foal at normal rates until the next gather is conducted. The post-gather sex ratio would be about 50:50 mares to studs. This would be expected to result in fewer and smaller bachelor bands, increased reproduction on a proportional basis within the herd, larger band sizes, and individual mares would likely begin actively producing at a slightly older age.

Impacts of Alternative 3 (Removal and Fertility Control)
Alternative 3 would involve fertility control, therefore, impacts related to fertility control would be the same as Alternative 1. The post-gather sex ratio would be about 50:50 mares to studs. This would be expected to result in fewer and smaller bachelor bands, increased reproduction on a proportional basis within the herd, larger band sizes, and individual mares would likely begin actively producing at a slightly older age.

Impacts of Alternative 4 (Removal and Sex Ratio Adjustment)
Alternative 2 would not involve fertility control, therefore, impacts related to fertility control would not apply. The post-gather sex ratio would be about 60:40 studs or geldings to mares. These impacts would similar to those discussed in Alternative 1.

Impacts of Alternative 5 (No Action)
Under the No Action Alternative, there would be no active management to control the population size within the established AML at this time. In the absence of a gather, wild horse populations would continue to grow at an average rate of 25% per year. Without a gather and removal now, the population would grow to 449 in four years based on the average annual growth rate.

Use by wild horses would continue to exceed the amount of forage allocated for their use. Competition between wildlife, livestock and wild horses for limited forage and water resources would continue. Damage to rangeland resources would continue or increase. Over time, the potential risks to the health of individual horses would increase, and the need for emergency removals to prevent their death from starvation or thirst would also increase. Over the long-term, the health and sustainability of the wild horse population is dependent upon achieving a thriving natural ecological balance and sustaining healthy rangelands. Allowing wild horses to die of dehydration or starvation would be inhumane and would be contrary to the WFRHBA which requires that excess wild horses be immediately removed. Allowing rangeland damage to continue to result from wild horse overpopulation would also be contrary to the WFRHBA which requires the BLM to "*protect the range from the deterioration associated with overpopulation*", "*remove excess animals from the range so as to achieve appropriate management levels*", and "*to preserve and maintain a thriving natural ecological balance and multiple-use relationship in that area*."

4.2.2 Grazing Management
Direct impacts to livestock and management practices from activity associated with gathering, including disturbance resulting from moving horses with a helicopter, would be minimal within the HMAs. Removal of horses from outside the HMAs may result in minimal livestock disturbance while herding wild horses into the HMAs.

Impacts Common to Action Alternatives (1-4)

Removal of approximately 275 head of horses from inside and outside the complex would reduce competition between livestock and wild horses for the available forage and water resources. Indirect impacts would include an increase in the quality and quantity of the available forage in the short-term. Over the longer-term, improved vegetation resources would lead to a thriving natural ecological condition.

Impacts of Alternative 1 (Removal, Sex Ratio Adjustment, and Fertility Control) – Impacts of removal would benefit livestock management opportunities due to limitations for forage and water resources as identified above. Those benefits would be extended by limiting future growth of the horse herd through sex ratio adjustments and fertility control.

***Impacts of Alternative 2 (Removal Only)* –** Impacts would not be as beneficial as in Alternative 1 and 3 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures or adjusting the sex ratio of the herd.

***Impacts of Alternative 3 (Removal and Fertility Control)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not adjusting the sex ratio of the herd.

***Impacts of Alternative 4 (Removal and Sex Ratio Adjustment)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures.

Impacts of Alternative 5 (No Action)

The current wild horse population is 10-20% above their forage allocation. Heavy to severe utilization is occurring in areas where wild horses concentrate. The indirect impacts of No Action (Defer Gather and Removal) would be continued damage to the range, continuing competition between livestock, wild horses and wildlife for the available forage and water, reduced quantity and quality of forage and water, and undue hardship on the livestock operators who would continue to be unable to fully use the forage resource they are authorized to use.

4.2.3 Wildlife

Impacts Common to Action Alternatives (1-4)

Wildlife currently using the project area would be exposed to the activities associated with horse gathers. The use of a helicopter would result in disturbance to wildlife, proportionate to the amount of time the helicopter is in use and the amount of ground that is covered. Effects would be of short duration (8 to 10 days) and localized. The effects to wildlife from trapping would be specific to the trap site.

Reducing horse numbers in this area would reduce the competition between horses and wildlife for the limited water and riparian habitat.

***Impacts of Alternative 2 (Removal Only)* –** Impacts would not be as beneficial as in Alternative 1 and 3 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures or adjusting the sex ratio of the herd.

***Impacts of Alternative 3 (Removal and Fertility Control)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not adjusting the sex ratio of the herd.

***Impacts of Alternative 4 (Removal and Sex Ratio Adjustment)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures.

Impacts of Alternative 5 (No Action)
Wildlife populations in the HMA would be forced to compete more for limited water and forage, which would most likely alter use patterns. Habitat degradation would decrease wildlife populations and wildlife use in the HMA.

4.2.4 Threatened and Endangered/Special Status Species

Impacts Common to Action Alternatives (1-4)
Reducing the number of wild horses in the HMA will lead to increased herbaceous cover as well as maintained or improved vegetative conditions. This will benefit sage grouse and other special status species identified in the affected environment by limiting habitat fragmentation and providing increased forage and vegetative structure required by the various life processes of these species. Habitat quality and quantity would be increased reducing potential threats to the species viability within the Barren Valley Complex.

Reducing the number of wild horses in the HMA would avoid unnecessary adverse impacts from wild horses to special status plants and their potential habitats in the Barren Valley Complex. Trap sites and off road access points used for the gather would be surveyed for special status plants prior to the gather in order to avoid known occurrence and potential habitats.

***Impacts of Alternative 2 (Removal Only)* –** Impacts would not be as beneficial as in Alternative 1 and 3 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures or adjusting the sex ratio of the herd.

***Impacts of Alternative 3 (Removal and Fertility Control)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not adjusting the sex ratio of the herd.

***Impacts of Alternative 4 (Removal and Sex Ratio Adjustment)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures.

Impacts of Alternative 5 (No Action)
Special status species would be affected by increased horse numbers through degradation of habitat conditions which could reduce productivity of these species. Riparian vegetation browsing and trampling springs, primarily due to wild horse use, would further degrade habitat conditions for wildlife.

4.2.5 Vegetation

Impacts Common to Action Alternatives (1-4)
In the immediate vicinity of the catch pens or corrals and the loading chute, short-term disturbance would occur. The soil would be compacted and vegetation would be trampled during panel installation by personnel and vehicles and severely trampled in the catch pen area by wild horses, domestic horses, and the wranglers. It is estimated and anticipated that 1 to 3 years would be required for native vegetation to become reestablished or regain vigor under average conditions with no reclamation. The total area of impact per trap would be approximately 2 acres, with less than ¼ acre severely disturbed. Less than one AUM of livestock forage would be temporarily lost for one grazing season at each trap site used.

There would be a positive impact to the upland and riparian vegetation by reducing the total numbers of wild horses grazing year long within the HMA. Lessened utilization would allow critical growth period rest for key cool season grasses. The composition of vegetation would change to a higher percentage of desirable plants, soil cover would increase and the potential for erosion would decrease.

Impacts of Alternative 1 (Removal, Sex Ratio Adjustment, and Fertility Control) – Impacts of removal would benefit vegetation resources as identified above. Those benefits would be extended by limiting future growth of the horse herd through sex ratio adjustments and fertility control.

***Impacts of Alternative 2 (Removal Only)* –** Impacts would not be as beneficial as in Alternative 1 and 3 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures or adjusting the sex ratio of the herd.

***Impacts of Alternative 3 (Removal and Fertility Control)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not adjusting the sex ratio of the herd.

***Impacts of Alternative 4 (Removal and Sex Ratio Adjustment)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures.

Impacts of Alternative 5 (No Action)
Areas which are presently over utilized, such as areas adjacent to water sources, would continue to be used excessively. The area of over utilization would continue to increase in both size and degree. The composition of vegetation would change to a higher percentage of undesirable plants, soil cover would be reduced, and the potential for erosion would increase.

4.2.6 Soils

Impacts Common to Action Alternatives (1-4)
Soil loss and compaction would be expected to decrease in those areas near water sources where horses are forced to concentrate. Lower populations of horses would result in less hoof traffic, thereby decreasing negative impacts to soil micro biotic crusts.

Soil would be displaced and/or compacted on approximately two acres at each site in the construction of the trap, use of the access routes, and in the round-up and loading of the wild horses. The area of severe surface disturbance is normally less than 2,000 square feet. Minimal surface wind and water erosion is expected on these areas during the vegetative rehabilitation period (approximately 1 to 3 years).

***Impacts of Alternative 2 (Removal Only)* –** Impacts would not be as beneficial as in Alternative 1 and 3 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures or adjusting the sex ratio of the herd.

***Impacts of Alternative 3 (Removal and Fertility Control)* -** Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not adjusting the sex ratio of the herd.

Impacts of Alternative 4 (Removal and Sex Ratio Adjustment) - Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures.

Impacts of Alternative 5 (No Action)
Soil loss and compaction would be expected to increase in those areas near water sources where horses are forced to concentrate. Increased wild horse numbers on uplands and riparian areas would negatively impact soil surface features and would increase erosion in the HMA.

4.2.7 Riparian Areas and Water Resources

Impacts Common to Action Alternatives (1-4)
The proposed action would limit the intensity of use at water sources and surrounding uplands. Regulating the number of wild horses in the HMA would reduce use near water sources and riparian areas by minimizing degradation to these resources.

The trap sites would not be located adjacent to any surface water sources or riparian areas, therefore, there would be no anticipated direct impact due to the gather.

Impacts of Alternative 2 (Removal Only) – Impacts would not be as beneficial as in Alternative 1 and 3 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures or adjusting the sex ratio of the herd.

Impacts of Alternative 3 (Removal and Fertility Control) - Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not adjusting the sex ratio of the herd.

Impacts of Alternative 4 (Removal and Sex Ratio Adjustment) - Impacts would not be as beneficial as in Alternative 1 due to the wild horse population increasing at a faster rate as a result of not conducting fertility control measures.

Impacts of Alternative 5 (No Action)
Increasing numbers of wild horses in the HMA would result in greater use and degradation of riparian areas. This would result in an unacceptable decline in water quality through increased sedimentation and water temperatures. Riparian area vegetation would be degraded as additional horse use would decrease vegetation recruitment, reproduction, and survivability. In addition, riparian vegetation community types and distribution would be changed, root density lessened, and canopy cover reduced. This would lead to reduced stream channel and spring/seep dynamics and further deterioration of these systems.

4.3 Cumulative Effects for All Alternatives

The NEPA regulations define cumulative impacts as impacts on the environment that result from the incremental impact of the Proposed Action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such actions (40 CFR 1508.7). Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. The cumulative impacts study area (CSA) for the purposes of evaluating cumulative impacts is the Barren Valley Complex.

According to the 1994 BLM *Guidelines for Assessing and Documenting Cumulative Impacts*, the cumulative analysis should be focused on those issues and resource values identified during scoping that are of major importance. Accordingly, the issues of major importance to be analyzed are maintaining rangeland health and proper management of wild horses.

Past and Present Actions

4.3.1 Wild Horses

Currently, management and AML of wild horses within the complex conforms to decisions in the SEORMP/ROD (2002) and the AMURMP/ROD (2005).

The actions which have influenced today's wild horse population are primarily wild horse gathers, which have resulted in the capture of some 7,352 wild horses, the removal of 6,919 excess horses, and release of 336 horses back into the HMA (see Table 3, Section 3.2.2).

4.3.2 Vegetation

Through land use planning decisions, the BLM has allocated the available forage to livestock, wildlife and domestic livestock. Additional benefits provided by healthy vegetation resources have resulted in land use planning decision to limit unacceptable impacts to vegetation. While the present livestock grazing system and efforts to manage the wild horse population within AML has reduced past historic impacts, monitoring indicates that the current overpopulation of wild horses is continuing to contribute to areas of heavy vegetation utilization, trailing and trampling damage and is preventing the BLM from managing for rangeland health and a thriving natural ecological balance and multiple use relationship on the public lands in the area.

4.4 Reasonably Foreseeable Future Actions

4.4.1 Wild Horses

Over the next 10-20 year period, reasonably foreseeable future actions include gathers about every 4 years to remove excess wild horses in order to manage population size within the established AML range. The excess animals removed would be transported to short-term corral facilities where they would be prepared for adoption, sale (with limitations), or LTPs. Any future wild horse management would be analyzed in appropriate environmental documents following site-specific planning with public involvement.

4.4.2 Vegetation

Continuing to graze livestock in a manner consistent with grazing permit terms and conditions would be expected to achieve or make significant progress towards achieving rangeland health standards and guidelines. Livestock grazing is expected to continue at similar stocking rates and utilization of the available vegetation (forage) would also be expected to continue at similar levels, with appropriate corrective actions implemented if current livestock management practices are found to contribute to not meeting rangeland health standards or guidelines. Similarly, appropriate actions would be implemented to adjust livestock grazing authorization terms and conditions, including livestock numbers and seasons of use, in the event that current livestock grazing practices are found to contribute to not meeting resource management objectives.

4.5 Summary of Past, Present, and Reasonably Foreseeable Future Actions

Impacts Common to Action Alternatives (1-4)

The cumulative effects associated with the capture and removal of excess wild horses includes gather-related mortality of less than 1% of the captured animals, about 5% per year associated with transportation, short term holding, adoption or sale with limitations and about 8% per year associated with long-term holding. This compares with natural mortality on the range ranging from about 5-8% per year for foals (animals under age 1), about 5% per year for horses ages 1-15, and 5-100% for animals age 16 and older (Stephen Jenkins, 1996, Garrott and Taylor, 1990). In situations where forage and/or water are limited, mortality rates increase, with the greatest impact to young foals, nursing mares and older horses.

The other cumulative effects which would be expected when incrementally adding either of the Action Alternatives to the CSA would include continued improvement of upland vegetation conditions, which would in turn benefit permitted livestock, native wildlife, and wild horse population as forage (habitat) quality and quantity is improved over the current level. Benefits from a reduced wild horse population would include fewer animals competing for limited forage and water resources. Cumulatively, there should be more stable wild horse populations, healthier rangelands, healthier wild horses, and fewer multiple use conflicts in the area over the short and long-term. Over the next 15-20 years, continuing to manage wild horses within the established AML range would achieve a thriving natural ecological balance and multiple use relationship on public lands in the area.

Impacts of Alternative 1 (Proposed Action)

Application of fertility control and adjustment in sex ratios to favor males should slow population growth and result in fewer gathers and less frequent disturbance to individual wild horses and the herd's social structure. However, return of wild horses back into the HMA could lead to decreased ability to effectively gather horses in the future as released horses learn to evade the helicopter.

Impacts of Alternative 2 (Removal Only)

Removal only of wild horses has been the predominant method of population control used in the past on this herd. This alternative will result in more frequent gathers and disturbance to the wild horses than Alternatives 1, 3 or 4. As wild horses are gathered and sorted through for selecting which animals to release back into the HMA, there could be a decrease in the ability to effectively gather horses in the future as released horses learn to evade the helicopter.

Impacts of Alternative 3 (Removal and Fertility Control)

Application of fertility control should slow population growth and result in fewer gathers and less frequent disturbance to individual wild horses and the herd's social structure. However, return of wild horses back into the HMA could lead to decreased ability to effectively gather horses in the future as released horses learn to evade the helicopter.

Impacts of Alternative 4 (Removal and Sex Ratio Adjustment)

Adjusting the sex ratio of the herd should slightly slow population growth and result in fewer gathers and less frequent disturbance to individual wild horses and the herd's social structure. However, return of wild horses back into the HMA could lead to decreased ability to effectively gather horses in the future as released horses learn to evade the helicopter.

Impacts of Alternative 5 (No Action)
Under the No Action Alternative, the wild horse population could exceed the low end of AML by approximately four or five times in four years. Movement outside the HMA would be expected as greater numbers of horses search for food and water for survival, thus impacting larger areas of public lands. Heavy to excessive utilization of the available forage would be expected and the water available for use could become increasingly limited. Eventually, ecological plant communities would be damaged to the extent that they are no longer sustainable and the wild horse population would be expected to crash.
Emergency removals could be expected under this alternative in order to prevent individual animals from suffering or death as a result of insufficient forage and water. These emergency removals could occur as early as FY 2012. During emergency conditions, competition for the available forage and water increases. This competition generally impacts the oldest and youngest horses as well as lactating mares first. These groups would experience substantial weight loss and diminished health, which could lead to their prolonged suffering and eventual death. If emergency actions are not taken, the overall population could be affected by severely skewed sex ratios towards stallions as they are generally the strongest and healthiest portion of the population. An altered age structure would also be expected.

Cumulative impacts would result in foregoing the opportunity to improve rangeland health and to properly manage wild horses in balance with the available forage and water and other multiple uses. Attainment of site-specific vegetation management objectives and Standards for Rangeland Health would not be achieved. AML would not be achieved and the opportunity to collect the scientific data necessary to re-evaluate AML levels, in relationship to rangeland health standards, would be foregone.

5.0 Monitoring and Mitigation Measures

The BLM Contracting Officer's Representative (COR) and Project Inspectors (PIs) assigned to the gather would be responsible for ensuring contract personnel abide by the contract specifications and the SOPs (Appendix A). Ongoing monitoring of forage condition and utilization, water availability, aerial population surveys, rangeland resources health, and animal health would continue.

Fertility control monitoring would be conducted in accordance with the SOPs (Appendix B). Monitoring the herd's social behavior would be incorporated into routine monitoring. The objective of this additional monitoring would be to determine if additional studs form bachelor bands or are more aggressive with breeding bands for the forage and water present.

If genetic monitoring indicates a loss of genetic diversity, then mares would be introduced into the Barren Valley Complex from an HMA with similar characteristics.

6.0 List of Preparers

The following list identifies the interdisciplinary team member's area of responsibility:

Shaney Rockefeller - Wild Horse and Burro Specialist, Vale District
Gary McFadden - Wild Horse and Burro Specialist, Burns District
Aimee Huff - Rangeland Management Specialist, Vale District
Marcella Egger - Rangeland Management Specialist, Vale District
Louis Clayburn - Rangeland Management Specialist, Burns District
Garth Ross - Wildlife Biologist, Fisheries, Vale District
Diane Pritchard – Archaeologist, Vale District
Lynne Silva, Weed Specialist, Vale District
Linus Meyer – Hydrologist, Soil Scientist, Riparian Management, Vale District
Gillian Wigglesworth – Botanist, ACEC/RNA Coordinator, Vale District
Caryn Meinicke – Botanist, Burns District
Kari Frederick – Recreation, VRM, Wilderness, Vale District
Eric Haakenson – Recreation, VRM, Wilderness, Burns District
Steve Christensen - Planning and Environmental Coordinator, Vale District
Rhonda Karges - Planning and Environmental Coordinator, Burns District
Carolyn Freeborn – Field Manager, Jordan Resource Area, Vale District
Joan Suther – Field Manager, Andrews Resource Area, Burns District

7.0 Consultation and Coordination

Public hearing(s) are held as a single state-wide hearing at the Burns District Office regarding the use of helicopters and motorized vehicles to capture wild horses (or burros). During the hearing(s), the public is given the opportunity to present new information and to voice any concerns or opinions regarding the use of these methods to capture wild horses (or burros). The Burns BLM Office held a hearing on May 4, 2010. One member of the pubic attended the meeting. BLM reviewed its Standard Operating Procedures in response to the views and issues expressed at the hearing and determined that no changes to the SOPs were warranted.

A notice of the action was sent to the groups and individuals on the Vale and Burns District Mailing Lists including wild horse and burro interest groups.

Livestock operators in the Barren Valley Complex have been consulted.

Coordination has been conducted with Oregon Department of Fish and Wildlife.

Appendix C – Win Equus Population Modeling Results
Map 1 – Barren Valley Complex

APPENDIX A

Standard Operating Procedures (SOPs) for Wild Horse (or Burro) Gathers

Gathers are conducted by utilizing contractors from the Wild Horse (or Burros) Gathers-Western States Contract or BLM personnel. The following procedures for gathering and handling wild horses apply whether a contractor or BLM personnel conduct a gather. For helicopter gathers conducted by BLM personnel, gather operations will be conducted in conformance with the *Wild Horse Aviation Management Handbook* (January 2009).

Prior to any gathering operation, the BLM will provide for a pre-capture evaluation of existing conditions in the gather area(s). The evaluation will include animal conditions, prevailing temperatures, drought conditions, soil conditions, road conditions, and a topographic map with wilderness boundaries, the location of fences, other physical barriers, and acceptable trap locations in relation to animal distribution. The evaluation will determine whether the proposed activities will necessitate the presence of a veterinarian during operations. If it is determined that a large number of animals may need to be euthanized or capture operations could be facilitated by a veterinarian, these services would be arranged before the capture would proceed. The contractor will be apprised of all conditions and will be given instructions regarding the capture and handling of animals to ensure their health and welfare is protected.

Trap sites and temporary holding sites will be located to reduce the likelihood of injury and stress to the animals, and to minimize potential damage to the natural resources of the area. These sites would be located on or near existing roads whenever possible.

The primary capture methods used in the performance of gather operations include:

1. Helicopter Drive Trapping. This capture method involves utilizing a helicopter to herd wild horses into a temporary trap.
2. Helicopter Assisted Roping. This capture method involves utilizing a helicopter to herd wild horses or burros to ropers.
3. Bait Trapping. This capture method involves utilizing bait (e.g., water or feed) to lure wild horses into a temporary trap.

The following procedures and stipulations will be followed to ensure the welfare, safety and humane treatment of wild horses in accordance with the provisions of 43 CFR 4700.

A. Capture Methods used in the Performance of Gather Contract Operations

1. The primary concern of the contractor is the safe and humane handling of all animals captured. All capture attempts shall incorporate the following:

All trap and holding facilities locations must be approved by the Contracting Officer's Representative (COR) and/or the Project Inspector (PI) prior to construction. The Contractor may also be required to change or move trap locations as determined by the COR/PI. All traps and holding facilities not located on public land must have prior written approval of the landowner.

2. The rate of movement and distance the animals travel shall not exceed limitations set by the COR/PI who will consider terrain, physical barriers, weather, condition of the animals and other

factors. Under normal circumstances this travel should not exceed 10 miles and may be much less dependent on existing conditions (i.e. ground conditions, animal health, extreme temperature (high and low)).

3. All traps, wings, and holding facilities shall be constructed, maintained and operated to handle the animals in a safe and humane manner and be in accordance with the following:

a. Traps and holding facilities shall be constructed of portable panels, the top of which shall not be less than 72 inches high for horses and 60 inches for burros, and the bottom rail of which shall not be more than 12 inches from ground level. All traps and holding facilities shall be oval or round in design.

b. All loading chute sides shall be a minimum of 6 feet high and shall be fully covered, plywood, metal without holes larger than 2"x4".

c. All runways shall be a minimum of 30 feet long and a minimum of 6 feet high for horses, and 5 feet high for burros, and shall be covered with plywood, burlap, plastic snow fence or like material a minimum of 1 foot to 5 feet above ground level for burros and 1 foot to 6 feet for horses. The location of the government furnished portable fly chute to restrain, age, or provide additional care for the animals shall be placed in the runway in a manner as instructed by or in concurrence with the COR/PI.

d. All crowding pens including the gates leading to the runways shall be covered with a material which prevents the animals from seeing out (plywood, burlap, plastic snow fence, etc.) and shall be covered a minimum of 1 foot to 5 feet above ground level for burros and 2 feet to 6 feet for horses

e. All pens and runways used for the movement and handling of animals shall be connected with hinged self-locking or sliding gates.

4. No modification of existing fences will be made without authorization from the COR/PI. The Contractor shall be responsible for restoration of any fence modification which he has made.

5. When dust conditions occur within or adjacent to the trap or holding facility, the Contractor shall be required to wet down the ground with water.

6. Alternate pens, within the holding facility shall be furnished by the Contractor to separate mares or jennies with small foals, sick and injured animals, estrays or other animals the COR determines need to be housed in a separate pen from the other animals. Animals shall be sorted as to age, number, size, temperament, sex, and condition when in the holding facility so as to minimize, to the extent possible, injury due to fighting and trampling. Under normal conditions, the government will require that animals be restrained for the purpose of determining an animal's age, sex, or other necessary procedures. In these instances, a portable restraining chute may be necessary and will be provided by the government. Alternate pens shall be furnished by the Contractor to hold animals if the specific gathering requires that animals be released back into the capture area(s). In areas requiring one or more satellite traps, and where a centralized holding facility is utilized, the contractor may be required

to provide additional holding pens to segregate animals transported from remote locations so they may be returned to their traditional ranges. Either segregation or temporary marking and later segregation will be at the discretion of the COR.

7. The Contractor shall provide animals held in the traps and/or holding facilities with a continuous supply of fresh clean water at a minimum rate of 10 gallons per animal per day. Animals held for 10 hours or more in the traps or holding facilities shall be provided good quality hay at the rate of not less than two pounds of hay per 100 pounds of estimated body weight per day. The contractor will supply certified weed free hay if required by State, County, and Federal regulation.

An animal that is held at a temporary holding facility through the night is defined as a horse/burro feed day. An animal that is held for only a portion of a day and is shipped or released does not constitute a feed day.

8. It is the responsibility of the Contractor to provide security to prevent loss, injury or death of captured animals until delivery to final destination.

9. The Contractor shall restrain sick or injured animals if treatment is necessary. The COR/PI will determine if animals must be euthanized and provide for the destruction of such animals. The Contractor may be required to humanely euthanize animals in the field and to dispose of the carcasses as directed by the COR/PI.

10. Animals shall be transported to their final destination from temporary holding facilities as quickly as possible after capture unless prior approval is granted by the COR for unusual circumstances. Animals to be released back into the HMA following gather operations may be held up to 21 days or as directed by the COR. Animals shall not be held in traps and/or temporary holding facilities on days when there is no work being conducted except as specified by the COR. The Contractor shall schedule shipments of animals to arrive at final destination between 7:00 a.m. and 4:00 p.m. No shipments shall be scheduled to arrive at final destination on Sunday and Federal holidays, unless prior approval has been obtained by the COR. Animals shall not be allowed to remain standing on trucks while not in transport for a combined period of greater than three (3) hours in any 24 hour period. Animals that are to be released back into the capture area may need to be transported back to the original trap site. This determination will be at the discretion of the COR/PI or Field Office horse specialist.

B. Capture Methods That May Be Used in the Performance of a Gather

1. Capture attempts may be accomplished by utilizing bait (feed, water, mineral licks) to lure animals into a temporary trap. If this capture method is selected, the following applies:

    a. Finger gates shall not be constructed of materials such as "T" posts, sharpened willows, etc., that may be injurious to animals.

    b. All trigger and/or trip gate devices must be approved by the COR/PI prior to capture of animals.

    c. Traps shall be checked a minimum of once every 10 hours.

2. Capture attempts may be accomplished by utilizing a helicopter to drive animals into a temporary trap. If the contractor selects this method the following applies:

    a. A minimum of two saddle-horses shall be immediately available at the trap site to accomplish roping if necessary. Roping shall be done as determined by the COR/PI. Under no circumstances shall animals be tied down for more than one half hour.

    b. The contractor shall assure that foals shall not be left behind, and orphaned.

3. Capture attempts may be accomplished by utilizing a helicopter to drive animals to ropers. If the contractor, with the approval of the COR/PI, selects this method the following applies:

    a. Under no circumstances shall animals be tied down for more than one hour.

    b. The contractor shall assure that foals shall not be left behind, or orphaned.

    c. The rate of movement and distance the animals travel shall not exceed limitations set by the COR/PI who will consider terrain, physical barriers, weather, condition of the animals and other factors.

C. Use of Motorized Equipment

1. All motorized equipment employed in the transportation of captured animals shall be in compliance with appropriate State and Federal laws and regulations applicable to the humane transportation of animals. The Contractor shall provide the COR/PI, if requested, with a current safety inspection (less than one year old) for all motorized equipment and tractor-trailers used to transport animals to final destination.

2. All motorized equipment, tractor-trailers, and stock trailers shall be in good repair, of adequate rated capacity, and operated so as to ensure that captured animals are transported without undue risk or injury.

3. Only tractor-trailers or stock trailers with a covered top shall be allowed for transporting animals from trap site(s) to temporary holding facilities, and from temporary holding facilities to final destination(s). Sides or stock racks of all trailers used for transporting animals shall be a minimum height of 6 feet 6 inches from the floor. Single deck tractor-trailers 40 feet or longer shall have at least two (2) partition gates providing at least three (3) compartments within the trailer to separate animals. Tractor-trailers less than 40 feet shall have at least one partition gate providing at least two (2) compartments within the trailer to separate the animals. Compartments in all tractor-trailers shall be of equal size plus or minus 10 percent. Each partition shall be a minimum of 6 feet high and shall have a minimum 5 foot wide swinging gate. The use of double deck tractor-trailers is unacceptable and shall not be allowed.

4. All tractor-trailers used to transport animals to final destination(s) shall be equipped with at least one (1) door at the rear end of the trailer which is capable of sliding either horizontally or vertically. The rear door(s) of tractor-trailers and stock trailers must be capable of opening the full width of the trailer. Panels facing the inside of all trailers must be free of sharp edges or holes that could cause injury to the animals. The material facing the inside of all trailers must be strong enough so that the

animals cannot push their hooves through the side. Final approval of tractor-trailers and stock trailers used to transport animals shall be held by the COR/PI.

5. Floors of tractor-trailers, stock trailers and loading chutes shall be covered and maintained with wood shavings to prevent the animals from slipping as much as possible during transport.

6. Animals to be loaded and transported in any trailer shall be as directed by the COR/PI and may include limitations on numbers according to age, size, sex, temperament and animal condition. The following minimum square feet per animal shall be allowed in all trailers:

11 square feet per adult horse (1.4 linear foot in an 8 foot wide trailer);
8 square feet per adult burro (1.0 linear foot in an 8 foot wide trailer);
6 square feet per horse foal (.75 linear foot in an 8 foot wide trailer);
4 square feet per burro foal (.50 linear feet in an 8 foot wide trailer).

7. The COR/PI shall consider the condition and size of the animals, weather conditions, distance to be transported, or other factors when planning for the movement of captured animals. The COR/PI shall provide for any brand and/or inspection services required for the captured animals.

8. If the COR/PI determines that dust conditions are such that the animals could be endangered during transportation, the Contractor will be instructed to adjust speed.

D. Safety and Communications

1. The Contractor shall have the means to communicate with the COR/PI and all contractor personnel engaged in the capture of wild horses utilizing a VHF/FM Transceiver or VHF/FM portable Two-Way radio. If communications are ineffective the government will take steps necessary to protect the welfare of the animals.

a. The proper operation, service and maintenance of all contractor furnished property is the responsibility of the Contractor. The BLM reserves the right to remove from service any contractor personnel or contractor furnished equipment which, in the opinion of the contracting officer or COR/PI violate contract rules, are unsafe or otherwise unsatisfactory. In this event, the Contractor will be notified in writing to furnish replacement personnel or equipment within 48 hours of notification. All such replacements must be approved in advance of operation by the Contracting Officer or his/her representative.

b. The Contractor shall obtain the necessary FCC licenses for the radio system

c. All accidents occurring during the performance of any task order shall be immediately reported to the COR/PI.

2. Should the contractor choose to utilize a helicopter the following will apply:

a. The Contractor must operate in compliance with Federal Aviation Regulations, Part 91. Pilots provided by the Contractor shall comply with the Contractor's Federal Aviation Certificates, applicable regulations of the State in which the gather is located.

b. Fueling operations shall not take place within 1,000 feet of animals.

E. Site Clearances

No personnel working at gather sites may excavate, remove, damage, or otherwise alter or deface or attempt to excavate, remove, damage or otherwise alter or deface any archaeological resource located on public lands or Indian lands.

Prior to setting up a trap or temporary holding facility, BLM will conduct all necessary surveys (archaeological, T&E, etc). All proposed site(s) must be inspected by a government archaeologist. Once archaeological survey has been conducted, the trap or temporary holding facility may be set up. Said surveys shall be arranged for by the COR, PI, or other BLM employees.

Gather sites and temporary holding facilities would not be constructed on wetlands or riparian zones.

F. Animal Characteristics and Behavior

Releases of wild horses would be near available water. If the area is new to them, a short-term adjustment period may be required while the wild horses become familiar with the new area.

G. Public Participation

Opportunities for public viewing (i.e. media, interested public) of gather operations will be made available to the extent possible; however, the primary considerations will be to protect the health, safety and welfare of the animals being gathered and the personnel involved. The public must adhere to guidance from the on-site BLM representative. It is BLM policy that the public will not be allowed to come into direct contact with wild horses or burros being held in BLM facilities. Only authorized BLM personnel or contractors may enter the corrals or directly handle the animals. The general public may not enter the corrals or directly handle the animals at anytime or for any reason during BLM operations.

H. Responsibility and Lines of Communication

Contracting Officer's Representative/Project Inspector
Shaney Rockefeller

Contracting Officer's Representative/Project Inspector
Gary McFadden

The Contracting Officer's Representatives (CORs) and the project inspectors (PIs) have the direct responsibility to ensure the Contractor's compliance with the contract stipulations. The Malheur Resource Area Assistant Field Manager and Field Manager will take an active role to ensure the appropriate lines of communication are established between the field, Field Office, State Office, National Program Office, and BLM Holding Facility offices. All employees involved in the gathering operations will keep the best interests of the animals at the forefront at all times.

All publicity, formal public contact and inquiries will be handled through the District Public Affairs Officer. This individual will be the primary contact and will coordinate with the COR/PI on any inquiries.

The COR will coordinate with the contractor and the BLM Corrals to ensure animals are being transported from the capture site in a safe and humane manner and are arriving in good condition.

The contract specifications require humane treatment and care of the animals during removal operations. These specifications are designed to minimize the risk of injury and death during and after capture of the animals. The specifications will be vigorously enforced.

Should the Contractor show negligence and/or not perform according to contract stipulations, he will be issued written instructions, stop work orders, or defaulted.

APPENDIX B

Standard Operating Procedures for Population-level Fertility Control Treatments

One-year liquid vaccine: The following implementation and monitoring requirements are part of the Proposed Action:

1. PZP vaccine would be administered through darting by trained BLM personnel or collaborating research partners only. For any darting operation, the designated personnel must have successfully completed a Nationally recognized wildlife darting course and who have documented and successful experience darting wildlife under field conditions.

2. Mares that have never been treated would receive 0.5 cc of PZP vaccine emulsified with 0.5 cc of Freund's Modified Adjuvant (FMA) and loaded into darts at the time a decision has been made to dart a specific mare. Mares identified for re-treatment receive 0.5 cc of the PZP vaccine emulsified with 0.5 cc of Freund's Incomplete Adjuvant (FIA).

3. The liquid dose of PZP vaccine is administered using 1.0 cc Pneu-Darts with 1.5" barbless needles fired from either Dan Inject® or Pneu-Dart® capture gun.

4. Only designated darters would mix the vaccine/adjuvant and prepare the emulsion. Vaccine-adjuvant emulsion would be loaded into darts at the darting site and delivered by means of a capture gun.

5. Delivery of the vaccine would be by intramuscular injection into the left or right hip/gluteal muscles while the mare is standing still.

6. Safety for both humans and the horse is the foremost consideration in deciding to dart a mare. The Dan Inject® gun would not be used at ranges in excess of 30 m while the Pneu-Dart® capture gun would not be used over 50 m, and no attempt would be taken when other persons are within a 30-m radius of the target animal.

7. No attempts would be taken in high wind or when the horse is standing at an angle where the dart could miss the hip/gluteal region and hit the rib cage. The ideal is when the dart would strike the skin of the horse at a perfect 90° angle.

8. If a loaded dart is not used within two hours of the time of loading, the contents would be transferred to a new dart before attempting another horse. If the dart is not used before the end of the day, it would be stored under refrigeration and the contents transferred to another dart the next day. Refrigerated darts would not be used in the field.

9. No more than two people should be present at the time of a darting. The second person is responsible for locating fired darts. The second person should also be responsible for identifying the horse and keeping onlookers at a safe distance.

10. To the extent possible, all darting would be carried out in a discrete manner. However, if darting is to be done within view of non-participants or members of the public, an explanation of the nature of the project would be carried out either immediately before or after the darting.

11. Attempts will be made to recover all darts. To the extent possible, all darts which are discharged and drop from the horse at the darting site would be recovered before another darting occurs. In exceptional situations, the site of a lost dart may be noted and marked, and recovery efforts made at a later time. All discharged darts would be examined after recovery in order to determine if the charge fired and the plunger fully expelled the vaccine.

12. All mares targeted for treatment will be clearly identifiable through photographs to enable researchers and HMA managers to positively identify the animals during the research project and at the time of removal during subsequent gathers.

13. Personnel conducting darting operations should be equipped with a two-way radio or cell phone to provide a communications link with the Project Veterinarian for advice and/or assistance. In the event of a veterinary emergency, darting personnel would immediately contact the Project Veterinarian, providing all available information concerning the nature and location of the incident.

14. In the event that a dart strikes a bone or imbeds in soft tissue and does not dislodge, the darter would follow the affected horse until the dart falls out or the horse can no longer be found. The darter would be responsible for daily observation of the horse until the situation is resolved.

22-month time-release pelleted vaccine: The following implementation and monitoring requirements are part of the Proposed Action:

1. PZP vaccine would be administered only by trained BLM personnel or collaborating research partners.

2. The fertility control drug is administered with two separate injections: (1) a liquid dose of PZP is administered using an 18-gauge needle primarily by hand injection; (2) the pellets are preloaded into a 14-gauge needle. These are delivered using a modified syringe and jabstick to inject the pellets into the gluteal muscles of the mares being returned to the range. The pellets are designed to release PZP over time similar to a time-release cold capsule.

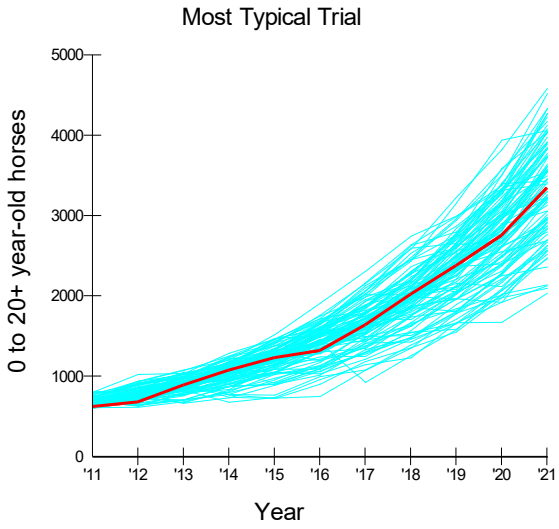
3. Delivery of the vaccine would be by intramuscular injection into the gluteal muscles while the mare is restrained in a working chute. The primer would consist of 0.5 cc of liquid PZP emulsified with 0.5 cc of Freunds Modified Adjuvant (FMA). The pellets would be loaded into the jabstick for the second injection. With each injection, the liquid or pellets would be injected into the left hind quarters of the mare, above the imaginary line that connects the point of the hip (hook bone) and the point of the buttocks (pin bone).

4. In the future, the vaccine may be administered remotely using an approved long range darting protocol and delivery system if or when that technology is developed.

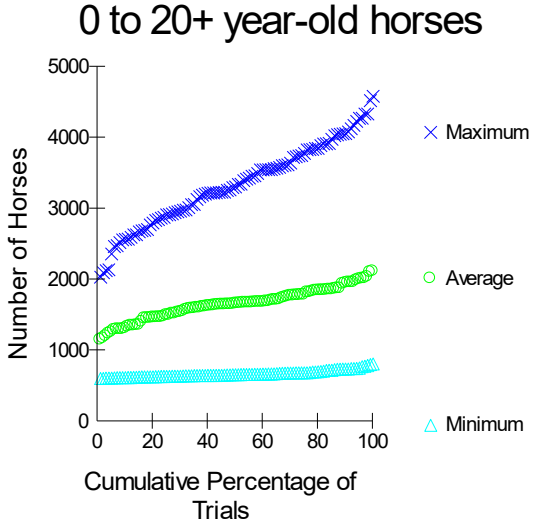
5. All treated mares will be freeze-marked on the hip or neck HMA managers to positively identify the animals during the research project and at the time of removal during subsequent gathers.

Monitoring and Tracking of Treatments:
1. At a minimum, estimation of population growth rates using helicopter or fixed-wing surveys will be conducted before any subsequent gather. During these surveys it is not necessary to identify which foals were born to which mares; only an estimate of population growth is needed (i.e. # of foals to # of adults).

2. Population growth rates of herds selected for intensive monitoring will be estimated every year post-treatment using helicopter or fixed-wing surveys. During these surveys it is not necessary to identify which foals were born to which mares, only an estimate of population growth is needed (i.e. # of foals to # of adults). If, during routine HMA field monitoring (on-the-ground), data describing mare to foal ratios can be collected, these data should also be shared with the NPO for possible analysis by the USGS.



3. A PZP Application Data sheet will be used by field applicators to record all pertinent data relating to identification of the mare (including photographs if mares are not freeze-marked) and date of treatment. Each applicator will submit a PZP Application Report and accompanying narrative and data sheets will be forwarded to the NPO (Reno, Nevada). A copy of the form and data sheets and any photos taken will be maintained at the field office.

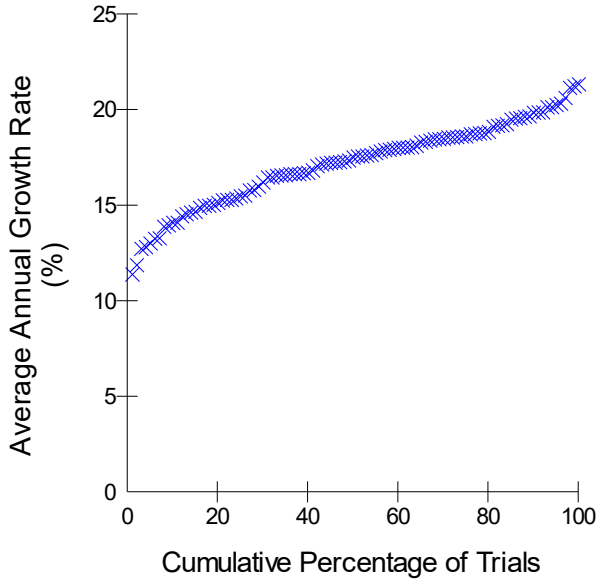


4. A tracking system will be maintained by NPO detailing the quantity of PZP issued, the quantity used, disposition of any unused PZP, the number of treated mares by HMA, field office, and State along with the freeze-mark(s) applied by HMA and date.

APPENDIX C

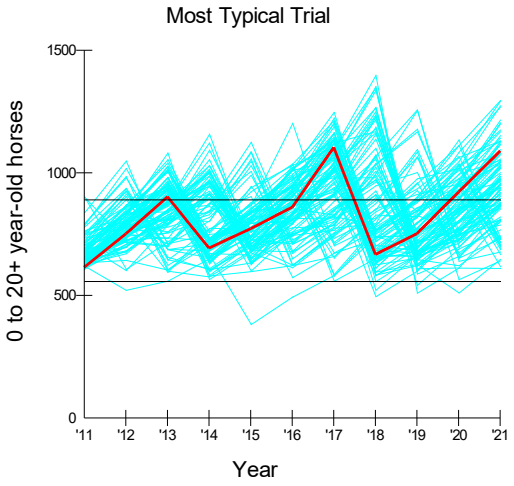
Population Modeling

Barren Valley Complex – No Action

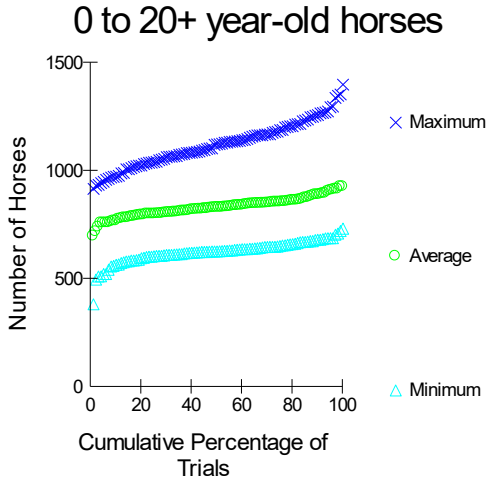


Population Sizes in 11 Years

	Minimum	Average	Maximum
Lowest Trial	606	1148	2037
10th Percentile	620	1321	2572
25th Percentile	637	1497	2918
Median Trial	660	1660	3328
75th Percentile	687	1799	3808
90th Percentile	741	1952	4075
Highest Trial	812	2113	4589



Barren Valley Comples – No Action (cont.)



Explanation:
In 11 years and 100 trials, the lowest number of 0 to 20+ year-old horses ever obtained was 606 and the highest was 4589. In half the trials, the minimum population size in 11 years was less than 660 and the maximum was less than 3328. The average population size across 11 years ranged from 1148 to 2113.

Average Growth Rate in 10 Years	
Lowest Trial	11.4
10th Percentile	14.1
25th Percentile	15.5
Median Trial	17.6
75th Percentile	18.7
90th Percentile	19.9
Highest Trial	21.4

Barren Valley Complex – Removal Only

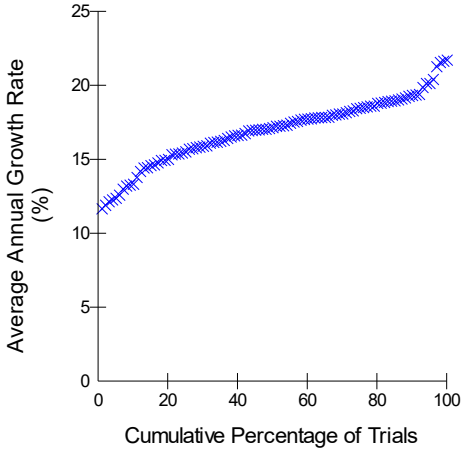
Population Sizes in 11 Years*

	Minimum	Average	Maximum
Lowest Trial	383	697	917
10th Percentile	566	771	976
25th Percentile	606	800	1042
Median Trial	628	830	1124
75th Percentile	654	856	1190
90th Percentile	682	890	1263
Highest Trial	733	926	1400

* 0 to 20+ year-old horses

Explanation:
In 11 years and 100 trials, the lowest number of 0 to 20+ year-old horses ever obtained was 383 and the highest was 1400. In half the trials, the minimum population size in 11 years was less than 628 and the maximum was less than 1124. The average population size across 11 years ranged from 697 to 926.

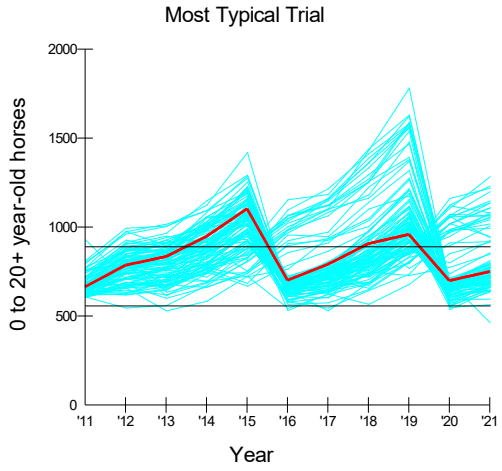
Barren Valley Complex – Removal Only (cont.)



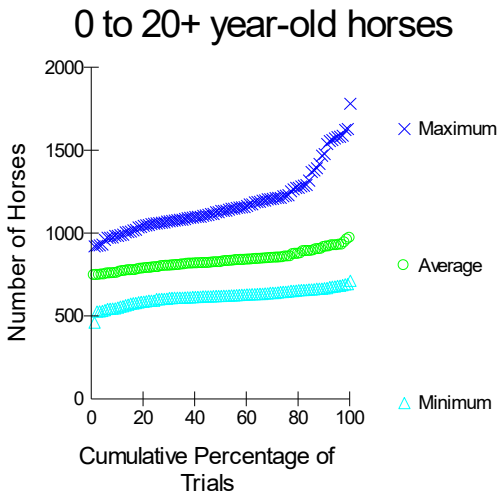
0 to 20+ year-old horses

Totals in 11 Years*

	Gathered	Removed
Lowest Trial	1000	682
10th Percentile	1164	805
25th Percentile	1378	992
Median Trial	1554	1106
75th Percentile	1984	1404
90th Percentile	2166	1553
Highest Trial	2541	1782



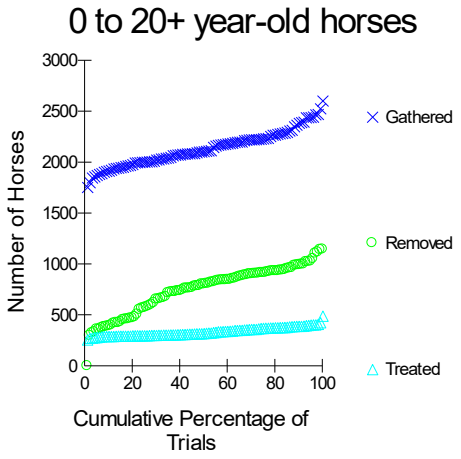
* 0 to 20+ year-old horses



Average Growth Rate in 10 Years

Lowest Trial	11.7
10th Percentile	13.6
25th Percentile	15.6
Median Trial	17.2
75th Percentile	18.5
90th Percentile	19.4
Highest Trial	21.8

Barren Valley Complex – Removal and Fertility Control and Removal with Fertility Control and Sex Ratio Skew



Population Sizes in 11 Years*

	Minimum	Average	Maximum
Lowest Trial	464	746	924
10th Percentile	557	763	990

1.0 Purpose and Need for Action

1.1 Introduction

The Bureau of Land Management (BLM) is proposing to gather excess wild horses in the Challis Herd Management Area (CHMA) in order to achieve the Appropriate Management Level (AML). The gather would occur for a 2 week period in the fall between September 15 and November 15. Approximately 274 wild horses would be gathered, and remove approximately 137 excess wild horses from within and outside the CHMA. Up to 137 of the captured wild horses would be released; of these, about 55 would be mares treated with fertility control and about 82 would be studs or geldings to maintain the sex ratio and slow population growth.

This Environmental Assessment (EA) is a site-specific analysis of the potential impacts that could result with the implementation of the Proposed Action or alternatives to the Proposed Action. Preparation of an EA assists the BLM authorized officer to determine whether to prepare an Environmental Impact Statement (EIS) if significant impacts could result, or a Finding of No Significant Impact (FONSI) if no significant impacts are expected.

This document is tiered to the Challis Resource Management Plan/Final EIS (RMP/EIS, 1999a).

1.2 Background

The CHMA is found in Custer County Idaho and consists of 168,720 total acres (154,150 BLM, 9,454 acres of State of Idaho lands, and 1,116 acres private lands near the East Fork of the Salmon River). The herd management area is bordered on the north by the Salmon River, on the west by the East Fork of the Salmon River, on the south by the ridgeline between Herd Creek and Road Creek and on the east by U.S. Highway 93 and the watershed boundary between the Salmon River drainage and the Lost River drainage.

The Appropriate Management Level (AML) for wild horses within the CHMA is 185. The AML was established in the October 1999 Challis Resource Management Plan EIS following an in-depth analysis of habitat suitability and resource monitoring and population inventory data, with public involvement. The AML for the CHMA is 185. The Challis RMP (CRMP) did recognize that between gathers the population would range up to 253. Two hundred and fifty-three (253) is the maximum number of wild horses that can graze in a thriving natural ecological balance and multiple use relationship on the public lands in the area.

The current estimated population of wild horses is 322 including wild horses residing in the CHMA and those outside the CHMA. This number is based on an aerial population inventory conducted as a direct count with multiple experienced observers immediately following the July 2009 gather, and prior to the release of gathered horses. The 57 animals the inventory identified on the range when coupled with the 167 animals released back into the CHMA following the gather, and the 3 following years foal increase result in a population of 322. Wild horse numbers have increased an average of 17% per year since the HMA was last gathered. The current population is about 174 animals over the AML.

The last wild horse gather of the CHMA occurred in July 2009, when 366 horses were captured, 141 horses were removed, 167 horses were released back into the CHMA. The 167 horses that

were released joined 57 horses that were not gathered, resulting in a 2009 post-gather population of 224 horses.

There are six allotments that are either partially or completely encompassed within the CHMA; including: Bradbury Flat, Bradshaw Basin, Mountain Springs, Road Creek, Split Hoof and Warm Springs. There are also two Areas of Critical Environmental Concern (ACEC) designated in the Challis RMP (USDI-BLM, 1999a), Malm Gulch/Germer Basin and Sand Hollow totaling 19,428 acres of "Frail Lands" where tuftaceous volcanic ash soils exist. These ACECs are part of the CHMA where wild horses have access, but are excluded to livestock grazing. Other ACECs in the CHMA include: Lone Bird, Antelope Flat, and East Fork Salmon River Bench. These ACECs contain a variety of unique features including pristine vegetation, rare plants, unusual plant assemblages, fragile soils, and cultural resource significance. The gather area involves two Wilderness Study Areas (WSAs): Corral-Horse Basin and Jerry Peak.

This environmental assessment (EA) evaluates the environmental effects of various alternatives the BLM has considered to maintain the CHMA wild horse AML.

This EA ensures compliance with the National Environmental Policy Act (NEPA) by providing site-specific analysis of potential direct, indirect, and cumulative effects to the human environment associated with completion of a gather and removal of excess wild horses in the CHMA. Should a determination be made that implementation of the Proposed Action or alternative actions would not result in significant environmental impacts, a FONSI would be prepared to document that determination, and a Decision Record providing the rationale for approving the chosen alternative would be issued.

Since the passage of the Wild Free-Roaming Horses and Burros Act (WFRHBA) of 1971, management knowledge regarding wild horse population levels has increased**.** By law, BLM is required to remove excess animals once a determination has been made that excess animals are present and removal is necessary. In the past two decades, program goals have shifted beyond establishing a *thriving natural ecological balance* (i.e. establishing AML for individual herds) and conducting gathers to achieve and maintain wild horse populations within the established AML so as to manage for a healthy wild horse populations and healthy rangelands. Management actions resulting from shifting the program emphasis include increasing fertility control and adjusting sex ratios to reduce population growth rates, increased gather intervals, improving the accuracy of population inventories and collecting genetic baseline data to support genetic health assessments. Decreasing removal numbers while reducing population growth rates and ensuring the welfare of wild horses on the range is pertinent to these program goals and consistent with findings and recommendations from the American Association of Equine Practitioners (AAEP), who recently issued a BLM Task Force Report in August 2011 following their evaluation of handling procedures and animal welfare at wild horse gathers, and short and long term sorting/holding facilities. The Executive Summary of this report stated: ―*Clearly the mission of the BLM Program – Healthy Ranges, Healthy Horses – is not a simple one. A central issue for all discussions involving the care and management of the wild horse population is controlling the reproductive rate of the wild horses on the range. The AAEP encourages the BLM to prioritize research and application of effective fertility control methods in order to reduce the foaling rate in wild herds"*

Public sentiment received for BLM gathers over the past few years have emphasized the desire for BLM to increase the use of fertility control in order to reduce the number of wild horses that have to be removed from the range or maintained in Long Term Pastures. This proposed gather is consistent with National BLM direction to increase the use of fertility control to maintain wild horses within AML with fewer necessary removals.

The following is a message from the BLM Director Bob Abbey: *"The BLM finds itself in the predicament of needing to gather overpopulated herds from the Western range each year while its holding costs keep rising – with no end in sight. Recognizing this unsustainable situation, the Government Accountability Office, in a report issued in October 2008, found the Bureau to be at a "critical crossroads" because of spiraling off-the-range holding costs and its limited management options concerning unadopted horses. In response, Secretary of the Interior Ken Salazar and I announced on October 7, 2009, a new and sustainable way forward for managing our nation's wild horse horses and burros. We recommended* ***applying new strategies aimed at balancing wild horse and burro population growth rates with public adoption demand to control holding costs*** **[emphasis in original]**. *This effort would involve slowing population growth rates of wild horses on Western public rangelands through the aggressive use of fertility control, the active management of sex ratios on the range, and perhaps even the introduction of non-reproducing herds in some of the BLM"s existing Herd Management Areas in 10 Western states"*. Refer to the entire message at
http://www.blm.gov/wo/st/en/prog/wild_horse_and_burro/national /about/director.html

The following is a quote from the Humane Society for the United States (HSUS): *"The HSUS strongly supports an increase in the use of fertility control – specifically the Porcine Zona Pellucida (PZP) immunocontraception vaccine – and sex ratio adjustments to slow population growth. This work should immediately be expanded to as many herds as possible as an alternative to gathers and long term holding. With an efficacy rate of over 90%, a comprehensive contraception program could dramatically reduce the financial burden on the agency and allow the BLM to once again focus its resources and efforts on range management programs" (HSUS 2010).*

To further implement this strategy of increasing population controls as a management tool, the 2012 BLM wild horse gather schedule increased emphasis to apply fertility control to reduce growth rates and thus the number of horses that must ultimately be removed from the range and either found adoptive homes or kept in long-term grazing pastures. This strategy‘s expected result is the removal of only limited numbers of excess wild horses for which there is the greatest adoption demand.

1.3 Purpose of and Need for Action

The Bureau of Land Management (BLM) Challis Field Office (CFO) is proposing to conduct a wild horse gather to remove excess wild horses from the Challis Herd Management Area (CHMA). The BLM is proposing to gather approximately 274 wild horses and remove approximately 137 excess wild horses from within and outside the CHMA in the fall. The purpose of the action is to address an excess population of wild horses, relative to the AML by

removing wild horses from the CHMA and all wild horses that have moved outside designated CHMA boundaries and to increase the interval between gathers.

The action is needed to be consistent with the established AML (USDI-BLM, 1999a) by removing excess wild horses from CHMA, and all horses outside the CHMA. This action would slow population growth rates, balance wild horse populations with herd health and other resources (Table 1). The action is needed to help prevent undue or unnecessary degradation of the public lands, protect rangeland resources from deterioration associated with excess wild horses within the CHMA, and would "restore a thriving natural ecological balance and multiple use relationship on the public lands consistent with the provisions of (P.L. 92-195 Section 1332 (b) (2) (as amended) of the *Wild Free-Roaming Horses and Burros Act WFRHBA of* 1971." Further, the action conducted in a humane, safe, efficient, and environmentally sound manner is needed to ensure current and future populations of healthy wild horses.

The Interior Board of Land Appeals (IBLA) has also held that "*Proper range management dictates removal of horses before the herd size causes damage to the rangeland. Thus, the optimum number of horses is somewhere below the number that would cause resource damage*" Animal Protection Institute, 118 IBLA 63, 75 (1991). The AML for CHMA needs to be achieved and maintained to prevent the decline of wild horse habitat and wildlife habitat and ensure long-term health and well-being of the wild horses. Maintaining wild horse populations consistent with the established AML would promote RMP and Allotment specific objectives, healthy riparian habitat, and maintaining or making progress towards attainment of Standards for Rangeland Health, and protection of ACECs and wilderness values in WSAs.

1.4 Land Use Plan Conformance

The Proposed Action is in conformance with the Challis Resource Management Plan (USDI-BLM, 1999a) under Wild Horses and Burros, Goal 1, Decision #1 "Manage the wild horse herd for an AML of 185 animals in accordance with the 1983 U.S. District Court Consent Judgment and the current activity plan for the wild horse CHMA"; Decision #3 "Monitor wild horse use of the Malm Gulch and Sand Hollow areas, and remove wild horses as necessary to protect fragile watersheds"; and Decision #7 "Adjust wild horse management to ensure progress toward the riparian and aquatic habitat conditions described in Attachment 1."

1.5 Appropriate Management Level (AML)

The AML was established through the Challis RMP (USDI-BLM, 1999a) process signed in 1999. The purpose of the RMP is to "*identify resource condition, objectives, land use allocations, and management actions and direction necessary to guide resource management on a long term, sustainable basis during the next 15-20 years*" (USDI-BLM, 1999a). The Challis RMP set the AML of 185 wild horses for the CHMA utilizing monitoring data, the Challis Experimental Stewardship Program sub-committee information, the 1976 Challis Herd Management Plan (CHMAP) and the 1989 CHMAP Update, as well as the Consent Judgment by United States District Judge Charles R. Richey. The Challis RMP also established objectives and goals of the CHMA stating "*The Herd would vary from 185 to 253 animals between roundups"*. The CRMP also allows the CFO to, "A*djust horse numbers to a lower level if causing unacceptable levels of resource degradation*".

The most recent helicopter inventory flight of the CHMA was conducted in 2009 immediately following the 2009 gather and before horses were released back to the CHMA, which resulted in a direct count of 57 wild horses. Once horses were released the wild horse population was 224. The 2012 estimated population based on 17% average annual increase (long-term average from inventory flights) is 322 wild horses (including foals) in the CHMA. The PZP fertility control was factored in for the 2011 year at 10% (fertility control for the treatment window, plus 90 mare's equaled 10% reproduction). The population estimate exceeds the established AML in the CHMA by 137 wild horses. Prior to the proposed gather, an inventory will be conducted to obtain a recent population inventory.

1.6 Relationship to Statutes, Regulations, Policy, Plans or other Environmental Analysis

The Proposed Action is in conformance with the WFRHBA of 1971 (Public Law 92-195, as amended), Section 302 (a) and (b) of the Federal Land Policy and Management Act (FLPMA) of 1976, the Public Rangelands Improvement Act of 1978 (Pub. L. 95-514, Sec. 4), the Code of Federal Regulations (CFR) at 43 CFR §4700, and policies. Applicable excerpts are as follows: *Where the Secretary determines . . . that overpopulation exists . . .* ***he shall immediately remove excess animals from the range*** *so as to achieve appropriate management levels. Such action shall be taken . . . until all excess animals have been removed so as to restore a thriving natural ecological balance to the range, and protect the range from the deterioration associated with overpopulation.*

The law also provides that determinations will be made ―*whether appropriate management levels should be achieved by the removal or destruction of excess animals,* ***or other options (such as sterilization, or natural controls on population levels)"*** [emphasis added].

FLPMA amended the WFRHBA with ―*In administering this Act, the Secretary may use or contract for the use of helicopters or, for the purpose of transporting captured animals, motor vehicles. Such use shall be undertaken only after a public hearing and under the direct supervision of the Secretary or of a duly authorized official or employee of the Department".*

PRIA directs the continued *"policy of protecting wild free-roaming horses and burros from capture, branding, harassment, or death, while at the same time facilitating the removal and disposal of excess wild free-roaming horses and burros which pose a threat to themselves and their habitat and to other rangeland values.*

BLM's Washington Office policy IM 2010-140, states in Section E: ―*During gather or herd management area planning, the authorized officer will consider a range of alternatives to reduce (slow) population growth rates and extend gather cycles for all wild horse herds with annual growth rates greater than or equal to 5%. These alternatives may include (but are not limited to): fertility control, adjustments in the sex ratio in favor of males, a combination of fertility control and sex ratio adjustment, and management of selected HMA for non-reproducing wild horses".* Similar direction is also located at Section 4.5.3 of the Wild Horses and Burros Management Handbook H 4700-1.

Statutes and Regulations
This action is governed by the **Wild Free Roaming Horse and Burro Act of 1971 (WFRHBA)** (Public Law (PL) 92-195 as amended) and Title 43 **Code of Federal Regulations (CFR)** part 4700. Gathering and disposal of the wild horses would be in accordance with PL 92-195 as amended by PL 94-579 **Federal Land Policy and Management Act (FLPMA)** and PL 95-514 **Public Rangelands Improvement Act (PRIA)**. Included are: **Section 302(b)** of FLPMA states that all public lands are to be managed so as to prevent unnecessary or undue degradation of the lands.

This action is in accordance with the following Federal Regulations:

43 CFR 4710.1, **Land Use Planning**
Management activities affecting wild horses and burros including the establishment of herd management areas shall be in accordance with approved land use plans pursuant to part 1600 of this title.

43 CFR 4710.2 Inventory and monitoring
The authorized officer shall maintain a record of the herd areas that existed in 1971, and a current inventory of the numbers of animals and their areas of use. When herd management areas are established, the authorized officer shall also inventory and monitor herd and habitat characteristics

43 CFR 4710.3-1 Herd Management Areas
Herd management areas shall be established for the maintenance of wild horse and burro herds. In delineating each herd management area, the authorized officer shall consider the appropriate management level for the herd, the habitat requirements of the animals, the relationships with other uses of the public and adjacent private lands, and the constraints contained in 4710.4. The authorized officer shall prepare a herd management area plan, which may cover one or more herd management area plans.

43 CFR 4710.4 Constraints on management.
Management of wild horses and burros shall be undertaken with the objective of limiting the animals' distribution to herd areas. Management shall be at the minimum feasible level necessary to attain the objectives identified in approved land use plans and herd management area plans.

43 CFR 4720.1 Removal of excess animals from public lands
Upon examination of current information and a determination by the authorized officer that an excess of wild horses or burros exists, the authorized officer shall remove the excess animals immediately.

43 CFR 4720.2-2 Removal of excess animals from private lands
If the authorized officer determines that proper management requires the removal of wild horses and burros from areas that include private lands, the authorized officer shall obtain the written consent of the private owner before entering such lands. **Flying aircraft over lands does not constitute entry.**

CFR 4740.1(a) (b) Use of motor vehicles or aircraft

(a) Motor vehicles and air craft may be used by the authorized officer in all phases of the administration of the Act, except that no motor vehicles or aircraft, other than helicopters, shall be used for the purpose of herding or chasing wild horses or burros for capture or destruction. All such use shall be conducted in a humane manner.
(b) Before using helicopters or motor vehicles… the authorized officer shall conduct a public hearing in the area where such use is to be made.

43 CFR 4770.1 Prohibited acts
The following acts are prohibited:

(a) Maliciously or negligently injuring or harassing a wild horse or burro;
(b) Removing or attempting to remove a wild horse or burro from the public lands without authorization from the authorized officer;
(c) Destroying a wild horse or burro without authorization from the authorized officer except as an act of mercy;
(d) Selling or attempting to sell, directly or indirectly, a wild horse or burro or its remains;
(e) Commercially exploiting a wild horse or burro;
(f) Treating a wild horse or burro inhumanely;
(g) Violating a term or condition of the Private Maintenance and Care Agreement;
(h) Branding a wild horse or burro
(i) Removing or altering a freeze mark on a wild horse or burro;
(j) Violating an order, term, or condition established by the authorized officer under this part.

43 CFR 4180.2(b), which states: "Standards and guidelines must provide for conformance with the fundamentals of rangeland health 4180.1."

The National Historic Preservation Act of 1966, as amended (NHPA; with regulations under 36 CFR 800) established the federal government's policy and programs on historic preservation. Section 106 of NHPA requires agencies to consider the effects of their actions on historic properties (defined as cultural resources determined to be eligible for listing on the National Register of Historic Places) prior to project implementation. The NHPA specifically requires federal agencies to identify and manage historic properties on federally owned and managed lands. Consultation under NHPA for the permit renewals has been conducted in accordance with BLM's National Programmatic Agreement and the implementing Protocol Agreement between Idaho BLM and the Idaho State Historic Preservation Office.

The *Fort Bridger Treaty of 1868* (15 Stat. 673) specifically reserves the rights of the Shoshone-Bannock Tribes to hunt, fish, gather, and exercise other traditional uses and practices on unoccupied federal lands, including public lands managed by the BLM-Challis Field Office. The federal government has a federal trust responsibility to manage public lands to provide for the continued exercise of tribal treaty rights, consistent with management policies, on all unoccupied lands within their jurisdiction. Part of the Federal trust responsibility entails conducting government-to-government consultation with Indian groups when a proposed project has the potential to impact the exercise of treaty-reserved rights.

The Clean Water Act (CWA) (33 USC §1251 et seq.) requires that states and tribes restore and maintain the chemical, physical, and biological integrity of the nation's waters. States and tribes must adopt water quality standards necessary to protect fish, shellfish, and wildlife while providing for recreation in and on the waters whenever possible.

Section 303(d) of the CWA establishes requirements for states and tribes to identify and publish a prioritized list of water bodies that are impaired (not fully supporting their designated beneficial uses, every two years). The most recent publication for Idaho was in 2010 by the Idaho Department of Environmental Quality (IDEQ). For waters identified on this list, the State must define total maximum daily loads (TMDLs) for each pollutant causing the water body not to fully support its designated beneficial uses. The TMDL is the amount of pollutant that could be added to the water body per day and the given water body would still fully support all of its designated beneficial uses. This is then used to establish allowable pollutant loads set at levels to achieve water quality standards required for the designated beneficial uses.

Section 7 of the Endangered Species Act (ESA) of 1973, as amended, outlines the procedures for Federal interagency cooperation to conserve federally listed species and designated critical habitat. Section 7(a) (2) states that each federal agency shall, in consultation with the Secretary, insure that any action it authorizes, funds, carries out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of its habitats.

Pursuant to Section 305(b)(2) of the Magnuson-Stevens Act, federal agencies must consult with the National Marine Fisheries Service (NMFS) regarding any of their actions authorized, funded, or undertaken, or proposed to be authorized, funded, or undertaken that may adversely affect Essential Fish Habitat (EFH). The Magnuson-Stevens Act, Section 3, defines EFH as “those waters and substrate necessary for fish for spawning, breeding, feeding, or growth to maturity.”

In 1995, the BLM adopted the Interim Strategy for Managing Anadromous Fish-Producing Watersheds in Eastern Oregon and Washington, Idaho, and Portions of California, commonly referred to as PACFISH (USDI-BLM 1995b). Also in 1995, the BLM implemented the Bull Trout Habitat Conservation Strategy known as INFISH (USDI-BLM 1995c). INFISH is virtually identical to PACFISH except that it applies to land management activities that influence bull trout habitats rather than anadromous fisheries habitats. INFISH standards apply to watersheds that are not already covered by PACFISH.

Sensitive plant inventories have been conducted on all proposed temporary capture sites and no populations have been discovered. If additional capture sites are needed plant clearances will occur prior to any action.

BLM Manual 6330, Management of Wilderness Study Areas, provides guidance on Wild Horse and Burro Management: Wild horse and burro herds are managed in WSAs only within geographic areas identified as having been used as a herd as its habitat in 1971 as directed by the Wild Free-Roaming Horse and Burro Act. Wild horses and burros are managed to remain in balance with the productive capacity of the habitat; this includes managing horses so as not to impair the wilderness characteristics. Wild horse and burro populations must be managed at appropriate management levels so as not to exceed the productive capacity of the habitat (as determined by available science and monitoring activities, to ensure a thriving natural ecological

balance, and to prevent impairment of the wilderness characteristics, watershed function, and ecological processes.

Helicopters and fixed wing aircraft may be used for the installation of new temporary facilities, for aerial surveys, for law enforcement activities, and for the gathering of wild horses and burros.

1.7 Conformance with Rangeland Health Standards and Guidelines

As stated in 43 CFR 4180.2(b) - ―Standards and guidelines must provide for conformance with the fundamentals of 43 CFR 4180.1. The Standards and Guidelines for Grazing Management for public lands have been reviewed by the Departmental Review Team who found that they comply with the requirements of the regulations. Gathering excess horses conforms to the Idaho standards and guides which are in conformance with appropriate land use plans.

1.8 Decision to be Made

The authorized officer's decision would determine whether to implement the proposed gather in order to bring the wild horse population to AML by maintaining or adjusting sex ratios and/or implementing fertility control measures (PZP-22 or current formula) in order to maintain population size within the established AML and avoid the deterioration of the range that can result from wild horse overpopulation. The authorized officer's decision would not set or adjust AML nor would it adjust livestock use, as these were set through previous decisions including the Challis RMP.

1.9 Scoping and Identification of Issues

As part of the preparation of this EA, a scoping letter dated February 3, 2012 was mailed to 41 individuals, agencies, and organizations on the interested public list for the Challis Herd Management Area, Wilderness List, and the associated Allotment Lists. In addition to the scoping letter an open house was held at the Challis Field Office on February 24, 2012 to answer questions and receive comments. Six comments were received at the Open House. Additionally, over 4,000 comments were received from interested publics during the scoping process. A statewide Helicopter Hearing for the use of motorized vehicles in the management of wild horses was held in Kimberly, Idaho on March 7, 2012. Six individuals attended and four commented on the use of helicopters. All of the individuals that commented supported the use of motorized vehicles in particular helicopters in the management of wild horses. Time was available following the meeting to comment on the proposed gathers in Challis and Boise.

The following issues were identified as a result of consultation/coordination and public scoping relative to the BLM's management of wild horses in the planning area:

- Population size and growth rate;
- Expected impacts to individual wild horses from handling stress;
- Expected impacts to herd social structure;
- Expected effectiveness of proposed fertility control application;
- Potential effects to genetic diversity;
- Potential impacts to animal health and condition;
- Impacts to individual wild horses and the Challis Herd.

2.0 Proposed Action and Alternatives

2.1 Introduction

This section of the EA describes the Proposed Action and alternatives, including any that were considered but eliminated from detailed analysis.

The authorized officer would determine whether to implement the proposed gather in order to bring the wild horse population back to AML by maintaining or adjusting sex ratios and/or implementing fertility control measures (PZP-22 or current formula) in order to maintain population size within the established AML and avoid the deterioration of the range that can result from wild horse overpopulation.

This section of the EA describes the Proposed Action and alternatives, including any that were considered but eliminated from detailed analysis. Five alternatives are considered in detail:

2.1.1 Alternative 1: Proposed Action

- Capture 274 wild horses or 85% of the population;
- Remove approximately 137 excess wild horses; including approximately 10 horses outside the CHMA;
- Treat all mares released back into the CHMA with PZP-22 fertility control vaccine at the sorting/holding facility
- Maintain the 60% male sex ratio as specified in the CHMAP revision of 1989.
- Wild horses captured from outside of the CHMA boundaries would be removed regardless of age and would not be released back into the CHMA.
- Field dart mares on private land adjacent to the CHMA if cooperating land owners and volunteers are willing to participate
- Photos of each mare treated with PZP-22 at the sorting/holding facility will be taken prior to release to assist in photo recognition to facilitate field darting trials in the future in the CHMA
- Photos would also be taken of individual mares prior to being field darted for photo recognition

2.1.2 Alternative 2: Removal Only

Capture and remove approximately 137 excess wild horses; including approximately 10 horses outside the CHMA with no fertility control and a 50/50 sex ratio adjustment.

2.1.3 Alternative 3: Removal with Fertility Control and Release of Geldings

- Selective removal of excess wild horses;
- Implementation of fertility control vaccine (PZP-22 or current formula);
- Maintain sex ratios to favor males (60:40);
- Achieving a post-gather population of 185 wild horses in the CHMA;
- A portion of the male population would be managed as a non-breeding population. The target sex ratio for the remaining breeding population would be 10:50:40 with a 10% gelding component;

2.1.4 Alternative 4: Removal with Fertility Control; without Sex Ratio Adjustment

- Capture and removal of approximately 137 excess wild horses, including approximately 10 wild horses from outside the CHMA;
- Administer PZP-22 fertility control vaccine to released mares and adjust the sex ratio to 50:50 from 60:40.

2.1.5 Alternative 5: No Action (Deferred Gather)

No Action — Defer gather and removal for a ten year period based on the Jenkins modeling program. This will display the possible ramifications of not gathering for a ten year period.

2.2 Management Actions Common to Alternatives 1-4

- The gather would begin about Mid-October and take 10 to 14 days to complete. Several factors such as animal condition, herd health, weather conditions, or other considerations could result in adjustments in the schedule.

- Gather operations would be conducted in accordance with the Standard Operating Procedures (SOPs) (Appendix B) described in the National Wild Horse and Burro Gather Contract (Appendix A). The primary gather (capture) methods would be the helicopter drive method with occasional helicopter assisted roping (from horseback).

- Existing capture sites and temporary sorting/holding facilities are located outside of riparian areas in previously used sites or other disturbed areas. Additional capture sites determined to be necessary for humane and effective gather operations will be located outside of stream riparian habitat conservation area (RHCA) buffers, consistent with the Challis RMP (USDI-BLM 1999a, Attachment 4, p. 83 – 84).

- Additional capture sites or sorting/holding facilities determined to be necessary for humane and effective gather operations would be inventoried for cultural resources and sensitive plants, and if present the capture sites and/or facilities would be established elsewhere.

- An Animal and Plant Health Inspection Service (APHIS) Doctor of Veterinary Medicine (DVM) or other licensed DVM will be on-site during the gather to examine animals and make recommendations to BLM for care and treatment of wild horses, and in accordance the 1999 Challis RMP Record of Decision (ROD) (pg. 90.)

- Decisions to humanely euthanize animals in field situations will be made in conformance with BLM policy (Washington Office Instruction Memorandum 2009-041). Current policy reference: http://www.blm.gov/wo/st/en/info/regulations/Instruction_Memos_and_Bulletins/national_instruction/2009/IM_2009-041.html

- Data including sex and age distribution, condition class information (using the Henneke rating system), color, size and other information may also be recorded, along with the disposition of that animal (removed or released).

- In accordance with IM 2009-062 hair samples should be collected every 10-15 years. DNA samples were last collected in 2002 placing the CHMA in the proper time frame for data collection. Hair samples would be collected on about 30 animals to assess the genetic diversity of the herd. Samples would also be collected during future gathers as needed to determine whether BLM's management is maintaining acceptable genetic diversity (avoiding inbreeding depression).

- Excess animals would be transported to the Challis BLM preparation facility where they will be prepared (freeze-marked, vaccinated and de-wormed) for adoption, sale (with limitations) or long-term holding.

- Temporary closure of roads within the CHMA during gather operations may be instituted as necessary to allow for safe and effective operations to proceed.

2.3 Description of Alternatives

2.3.1 Alternative 1. Proposed Action

The Proposed Action would gather about 274 or 85% of the population of wild horses beginning about Mid-October, in order to remove approximately 137 excess wild horses, apply PZP-22 fertility control vaccine to 55 released mares, and maintain a 60% male sex ratio. Wild horses captured from outside of the CHMA boundaries would be removed regardless of age and would not be released back into the CHMA. Animals would be removed using the National Selective Removal Policy IM 2010-164 (Appendix F). Selective removal criteria for the CHMA include: 1) First Priority: Age Class – Four Years and Younger; 2) Second Priority: Age Class – Eleven to Nineteen Years 3) Third Priority: Age Class Five to Ten Years 4) Fourth Priority: Age Class Twenty Years and Older should not be removed from the CHMA unless specific exceptions prevent them from being turned back to the range.

Mares would be treated with a two-year PZP-22 or most current formulation or similar vaccine and released back to the range. Fertility control treatment would be conducted in accordance with the approved standard operating and post-treatment monitoring procedures (SOPs, Appendix B). Mares would be selected to maintain a diverse age structure, herd characteristics and conformation (body type).

Stallions and geldings would be selected for release with the objective of maintaining the 60% male sex ratio. Stallions would be selected to maintain a diverse age structure, herd characteristics and body type (conformation).

The primary gather technique would be the helicopter-drive trapping method. The use of roping from horseback could also be used when necessary. Multiple capture sites may be used to gather wild horses both from within and outside the CHMA. The existing potential capture sites are depicted on Map 8. Any new capture sites or areas designated for sorting/holding facilities would be analyzed prior to use.

Capture sites would be limited to roads or outside active riparian areas or cultural resource sites. Capture sites within WSAs would be restricted to existing roads. No additional capture sites would be set up within known populations of Sensitive Species; any new additional capture sites not depicted on Map 8 would be constructed outside of the RHCA to preclude impacts to riparian areas or aquatic resources. Sites may be monitored for invasive or non-native species for the next several years to verify that these species are not present and do not become established. The capture sites and sorting/holding facilities may be seeded with native seed mixes if deemed necessary by the authorizing officer. These capture sites are used for short time frame of one to three days. However; prior experience has shown sorting/holding facilities may receive sufficient disturbance to require seeding due to longer duration of horses being present and larger numbers of horses. Sorting/holding site selections would follow SOPs (Appendix B).

Following the capture of wild horses, animals would be sorted by age and sex, and selected for release back to the CHMA or for transport to the Challis Wild Horse Preparation Facility. Table 2 displays the anticipated gather and removal figures.

Most foals would be removed and transported to the Challis wild horse preparation facilities as they would be 5-7 months of age and weaned from their dams. If foals too young to wean are encountered they would be released with their dam. If the dam is unable to be released they would be kept together and the foal would not be weaned until of an appropriate age. Due to the timing of the gather in mid-October the occurrence of foals too small to wean would be rare.

Herd health and characteristics data would be collected as part of continued monitoring of the wild horse herds. Other data, including sex and age distribution, condition class information (using the Henneke rating system), color, size and other information may also be recorded for all gathered wild horses. Genetic data would be collected from approximately 30 individuals to monitor the genetic health of the wild horses within the CHMA and compare samples taken in 2002.

Gathered wild horses would be transported to Challis BLM preparation facility or other BLM facilities where they would be prepared for adoption and/or sale to qualified individuals who could provide them with a good home or for transfer to long-term grassland pastures.

Limited bait (food/mineral) trapping may be utilized to achieve the management targets or to relieve specific resource or human safety concerns within and adjacent to the CHMA.

Wild horses would be selected and released back to the CHMA, so as to represent the historic characteristics of the CHMA. This would include selecting animals of moderate or larger stature, average or better confirmation, 20% grey coloration as well as the historic range of colors found within the CHMA. Animals that exhibit exceptional characteristics may be chosen for release outside of the selective removal priorities on a case by case basis. Wild horses to be released would be selected for health, stamina, strength and mothering abilities when these factors can be determined. Weak, unhealthy, and unthrifty animals would not be selected for release back into the CHMA. A helicopter inventory flight may be conducted following the gather to collect information about numbers and distribution of remaining wild horses within the CHMA.

An APHIS DVM or other licensed DVM would be on-site during the gather, as needed, to examine animals and make recommendations to the BLM for care and treatment of wild horses. All excess wild horses removed from within and outside the CHMA would be made available for adoption or sale to qualified individuals.

Any old, sick or lame horses unable to maintain an acceptable body condition (greater than or equal to a Henneke body condition score of 3 or with serious physical defects such as club feet, severe limb deformities, parrot mouth, or sway back would be humanely euthanized as an act of mercy. Decisions to humanely euthanize animals in field situations would be made in conformance with BLM policy (Washington Office Instruction Memorandum 2009-041).Refer to:
http://www.blm.gov/wo/st/en/info/regulations/Instruction_Memos_and_Bulletins/national_instruction/2009/IM_2009-041.html

2.3.2 Alternative 2: Removal Only

Alternative 2 would gather about 274 and remove approximately 137 excess wild horses from within and outside the CHMA beginning about Mid-October. Fertility control **would not be** applied; and the herd's sex ratio would be returned to 50:50.

2.3.3 Alternative 3: Removal with Fertility Control and Release of Geldings

Alternative 3 would gather about 274 and remove approximately 137 excess wild horses from within and outside the CHMA beginning about Mid-October. Fertility control would be applied, as stated in the proposed alternative; the herd's *breeding* sex ratio would be 50:40 stallions to mares. Geldings would make up an additional 10% of the herd acting as a non-reproductive component of the herd. The population would then be comprised of 40% mares and 60% mixed stallions and geldings.

2.3.4 Alternative 4: Removal with Fertility Control; without Sex Ratio Adjustment

Alternative 4 would gather about 274 and remove approximately 137 excess wild horses from within and outside the CHMA beginning about Mid-October. Fertility control would be applied but the sex ratio would return to 50:50.

2.3.5 Alternative 5: No Action (Deferred Gather)

No Action — Defer gather and removal for a ten year period based on the Jenkins modeling program. This would display the possible ramifications of not gathering for a ten year period.

The Proposed Action, Alternative 2, Alternative 3 and Alternative 4 were developed to respond to the identified resource issues and the Purpose and Need to differing degrees. The No Action Alternative would not achieve the identified Purpose and Need. However, it is analyzed in this EA to provide a basis for comparison with the other action alternatives, and to assess the effects of not conducting a gather at this time. The No Action Alternative is in violation of the WFRHBA which requires the BLM to immediately remove excess wild horses, additionally it is not in conformance with regulatory provisions for management of wild horses and burros as set forth at 43 CFR § 4700.

2.4 Alternatives Considered but Eliminated from Detailed Analysis

2.4.1 Water or Bait Trapping as the exclusive gather method

An alternative considered but dismissed from detailed analysis was use of water, bait (food/mineral) trapping as the primary gather method, instead of a helicopter gather. Though the use of water or bait trapping to remove excess wild horses and burros can be fairly effective on a small scale and under specific conditions and circumstances, this alternative was dismissed from detailed study for the following reasons: 1) the area within the CHMA is too rugged to access effectively during the most favorable times to gather; 2) the presence of widely spread water sources in the form of perennial springs and streams make it nearly impossible to restrict wild horse access to only selected water capture sites. The difficult terrain involved and the extended time necessary for implementation of this alternative would result in a substantial increase in gather costs and would make it difficult to limit the gather to the preferred winter months to take advantage of the recommended fertility control application period. Given the impracticalities of implementing this alternative for such a difficult geographic area, this alternative was eliminated from detailed study as the sole gather method. This method may be used in a limited approach on a case by case basis.

2.4.2 Remove or Reduce Livestock within the CHMA

This alternative would involve no removal of wild horses and instead address the excess wild horse numbers through the removal or reduction of livestock within the CHMA. This alternative was not brought forward for analysis because it is inconsistent with the Challis RMP and ROD and is inconsistent with multiple use management.

The proposal to reduce livestock would not meet the purpose and need for action identified in Section 1.3 "*to remove excess wild horses in the HMA. This action is needed in order to achieve a population size within the established AML, protect rangeland resources from further deterioration associated with the current wild horse overpopulation, and restore a thriving natural ecological balance and multiple use relationship in the area consistent with the provisions of Section 3(b) (2) of the Wild Free-Roaming Horses and Burros Act of 1971 (1971 WFRHBA)". R*educing horse populations to within AML is necessary in order to evaluate if wild horse management at AML would allow BLM to meet rangeland health standards.

The total authorized livestock AUMs with the upper range of AML in AUMs and the total wild horse population in AUMs for 2011 can be found in Table 9.

This alternative is also inconsistent with the WFRHBA, which directs the Secretary to immediately remove excess wild horses. Livestock grazing can only be reduced or eliminated if BLM follows regulations at 43 CFR § 4100 and must be consistent with multiple use allocations set forth in the land-use plan. Such changes to livestock grazing cannot be made through a wild horse gather decision, and are only possible if BLM first revises the land-use plans to allocate livestock forage to wild horses and to eliminate or reduce livestock grazing.

Furthermore, re-allocation of livestock AUMs to increase the wild horse/burro AMLs would not achieve a thriving natural ecological balance. Unlike livestock which can be confined to specific pastures, limited periods of use, and specific seasons-of-use so as to minimize impacts to

vegetation during the critical growing season or to riparian zones during the summer months, wild horses are present year-round and their impacts to rangeland resources cannot be controlled through establishment of a grazing system, such as for livestock. Thus, impacts from wild horses and burros can only be addressed by limiting their numbers to a level that does not adversely impact rangeland resources and other multiple uses. For the reasons stated above, this alternative was dropped from detailed analysis. Changes in forage allocations between livestock and wild horses/burros would have to be re-evaluated and implemented through the appropriate public decision-making processes to determine whether a thriving natural ecological balance can be achieved at a higher AML and in order to modify the current multiple use relationship established in the land-use plan.

2.4.3 Control the excess wild horses with only the use of fertility control treatment

An alternative to gather a significant portion of the existing population (95%) and implement fertility control treatments only, without removal of excess horses, was modeled using a three-year gather/treatment interval over a 20 year period. The wild horse population would continue to have an average population growth rate of 0.8% to 6.0 %, adding to the current wild horse overpopulation, albeit at a slower rate of growth. Over the next 20 years, on average the population would grow to between 322 and 1725 wild horses with the resulting population being between 130 and 1540 horses over AML. In order to accomplish the reduced rates of growth between 1435 and 1970 horses would need to be gathered and treated. This alternative would not bring the horse population to AML and would allow the wild horse population to continue to grow even further in excess of AML, resource concerns would escalate, and implementation of this alternative would result in significantly increased gather and fertility control costs without achieving a thriving natural ecological balance. This method has been used with small numbers of horses that are conditioned to human presence and easily approached. This alternative would not meet the purpose and need. It would not comply with the WFRHBA because it would not remove excess wild horses from the range and would not restore a thriving ecological balance to the ecosystem. The complete model trial data are described below in Table 1.

Table 1. WinEquus gather and treat data without removal

	Population Size in 11 Years*		
	Gathered	Removed	Treated
Lowest Trial	1052	0	306
10th Percentile	1328	0	415
25th Percentile	1530	0	465
Median Trial	1760	0	540
75th Percentile	1940	0	604
90th Percentile	2116	0	660
Highest Trial	2561	0	833

* 0 to 20+ year-old horses Parameters used in the modeling include the following assumptions:

Each time a horse is gathered it is counted, even though the same horse may be gathered multiple times during the 11 year period.

Each time a horse is treated with PZP-22 it is counted, even though the same horse may be treated multiple times over the 11 year period.

2.4.4 Gather Portion of Existing Population, Incremental reduction of Wild Horses, Evaluation of Habitat Response

An alternative to gather a significant portion of the existing population (85%) remove only a portion of the excess wild horse population (67 horses) and implement fertility control was recommended through the public review process. Implementation of this alternative would reduce the existing population by 16-18%, but the remaining wild horse population would be anticipated to increase at an average fertility rate of 17% (based upon average number of foals counted during population inventories) annually. This rate of increase would fully offset the 67 horses that would be removed as of the 2013 foal crop and no significant progress would be made in reducing resource impacts from the current overpopulation of wild horses within the CHMA. This alternative would not result in attainment of AML for the CHMA as required by under the WFRHBA.

Additionally, AML represents "*that optimum number of wild horses/burros which results in a thriving natural ecological balance and avoids a deterioration of the range*." (Animal Protection Institute, 109 IBLA 119 1989). The Interior Board of Land Appeals has also held that "Proper range management dictates removal of horses *before the herd size causes damage to the range land*. Thus, the optimum number of horses is somewhere below the number that would cause resource damage" Animal Protection Institute, 118 IBLA 63, 75 (1991) (italics added). The AML is set to prevent range deterioration and allow for allocation of forage for other use in compliance with our multiple use mission. For these reasons, this alternative was eliminated from further consideration.

2.4.5 Alternative Capture Techniques

An alternative using capture methods other than helicopters to gather excess wild horses was suggested through the public review process. The following optional methods were recommended through scoping; chemical immobilization, net gunning, and wrangler/horseback drive capture as potential methods for gathering horses. Net gunning techniques normally used to capture big game animals also rely on helicopters. Chemical immobilization is a very specialized technique and strictly regulated. Currently the BLM does not have sufficient expertise to implement either of these methods and it would be impractical to use given the size of the project area and the number of horses that would need to be removed, access limitations and difficulties in approachability of the horses. Each of these techniques may also increase mortality for wild horses as well as wranglers and domestic horses.

Use of wrangler on horseback drive-trapping to remove excess wild horses can be fairly effective on a small scale. However, given topography, terrain and difficulties in approaching the horses this technique would be ineffective and impractical. Horseback drive-trapping is also very labor intensive and can be very harmful to the domestic horses and the wranglers used to herd the wild horses. Domestic horses can easily be injured while covering rough terrain and the wrangler could be injured if he/she falls off. For these reasons, this alternative was eliminated from further consideration.

2.4.6 Density Dependent Mortality

While some members of the public have advocated "letting nature take its course", allowing horses to die of starvation would be inhumane treatment and would be contrary to the WFRHBA,

which mandates removal of excess wild horses. The damage to rangeland resources that results from excess numbers of wild horses is also contrary to the WFRHBA, which mandates the Bureau to "*protect the range from the deterioration associated with overpopulation*", "*remove excess animals from the range so as to achieve appropriate management levels*", and *"to preserve and maintain a thriving natural ecological balance and multiple-use relationship in that area"*. Once the vegetative resources are at these critically low levels due to excessive utilization by an over population of wild horses, the weaker animals, generally the older animals, and the mares and foals, are the first to be impacted. It is likely that a majority of these animals would die from starvation. The resultant population would be heavily skewed towards the stronger stallions which would lead to significant social disruption in the CHMA. By managing the public lands in this way, the vegetative resources would be impacted first and to the point that they have no potential for recovery. Competition between livestock, wildlife and wild horses for forage and water resources would continue, and worsen as wild horse numbers continue to increase above AML and would conflict with BLM's multiple use mission.

2.4.7 Designation of the CHMA to be Managed Principally for Wild Horses.

Designate the CHMA as "Wild Horse Range". This action under 43 CFR 4710.3-2 would require amendment of the 1999 Challis RMP, which is outside the scope of this EA. Only the BLM Director or Assistant Director (as per BLM Manual 1203: Delegation of Authority), may establish a Wild Horse and Burro Range after a full assessment of the impact on other resources through the land-use planning process. Wild Horse and Burro Range is not an "exclusive" designation. Designation would not necessarily exclude livestock use; therefore levels of livestock grazing permitted could remain the same. The CHMA has not been designated as a wild horse range under 43 CFR 4710.3-2.2. Currently there are four designated Wild Horse and Burro Ranges in the Western United States that are managed principally for wild horses and burros consistent with 43 CFR 4170.3-2.2. These are the Pryor Mountain Wild Horse Range in Montana; the Little Book Cliffs Wild Horse Range in Colorado; the Nevada Wild Horse Range and the Marietta Wild Burro Range in Nevada.

Table 2. Summary and Comparison of Impacts to Wild Horses by Alternative

	Alt 1: Proposed Action	**Alt 2: Removal Only**	**Alt 3: 10% Geldings Removal and Fertility Control only**	**Alt 4: Removal and Sex Ratio only**	**Alt 5: No Action**
Gather Number	274	274	274	274	0
Removal Number	137	137	137	137	0
Fertility Control - # Mares Treated	55	0	55	0	0
Post-Gather Sex Ratio	60/40*	50/50	60/40 or 10/50/40 Gelding/Stallion/ Mare	60/40	Unknown
Post-Gather Population	185	185	185	185	322

*The 1989 Challis Herd Management Plan Update changed the sex ratio to 60/40 males to females

3.0 Affected Environment and Environmental Effects

To comply with the National Environmental Policy Act (NEPA), the Bureau of Land Management is required to address specific elements of the environment that are subject to requirements specified in statute or regulation or by executive order. The following table outlines the elements that must be addressed in all environmental analyses, as well as other resources deemed appropriate for evaluation by the BLM, and denotes if the Proposed Action, sequential alternatives, or the No Action Alternative affects those elements.

Potential or expected impacts to the affected resources are discussed following the table. Direct impacts are those that result from the actual implementation of the chosen alternative. Indirect impacts are those impacts that occur once an alternative has been implemented.

Table 3. Resources Considered in Impact Analysis

Resource	**Present Yes/No**	**Affected Yes/No**	**Rationale**
Air Quality	**Yes**	**No**	The implementation of all alternatives including the no action alternative would not result in the production of vehicle or equipment emission or particulate matter above incidental levels. Short term dust would be present at capture sites.
Areas of Critical Environmental	**Yes**	**No**	There are five Areas of Critical Environmental Concern (ACEC) within the CHMA. They are:

Table 3. Resources Considered in Impact Analysis			
Resource	**Present Yes/No**	**Affected Yes/No**	**Rationale**
Concern (ACEC's)			Malm Gulch/Germer Basin, Lone Bird, Antelope Flat, East Fork Salmon River Bench and Sand Hollow. These ACECs contain a variety of unique features including pristine vegetation, rare plants, unusual plant assemblages, fragile soils and cultural resource significance. No capture sites would be built in an ACEC.
Cultural Resources	**Yes**	**No**	Intensive survey for cultural resources in and near gather-related congregation areas (e.g., proposed capture sites, sorting/holding facilities) has occurred in 1986, 1994, and 2004. These specific areas are used recurrently to support gathers. If additional gather-related congregation areas are determined necessary for the 2012 wild horse gather, inventory and review for cultural resources impacts would occur prior to project implementation. Impacts to properties eligible for listing on the National Register of Historic Places would be avoided, in accordance with the 2012 revision of the BLM's National Programmatic Agreement and the implementing Protocol Agreement between Idaho BLM and the Idaho State Historic Preservation Office. Adherence of the Standard Operating Procedures (SOPs) (Appendix B), would mitigate many potential impacts to historic properties.
Environmental Justice	**No**	**No**	There are no minority or low income populations residing near the proposed project area.
Existing and Potential Land Uses	**No**	**No**	The proposed action would not affect the study areas current and likely future use as a grazing allotment.
Farmlands (prime and unique)	**No**	**No**	There are no prime or unique farmlands in the vicinity of the project area.
Floodplains	**No**	**No**	Based on the FEMA Flood Insurance Study, this allotment occurs in Zone D, an area where no floodplains have been delineated and no flood hazards have been identified (FEMA 1988).
Forest Resources	**Yes**	**No**	There are forest resources in the project area located at high elevations with limited vehicle access. Therefore, Forest Resources would not be affected by the proposed action.
Grazing/Livestock Management	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Invasive, Non-Native Species	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Lands with Wilderness	**No**	**No**	The Challis CHMA overlaps with 6 LWC Inventory units. Three of the units were initially

Table 3. Resources Considered in Impact Analysis			
Resource	**Present Yes/No**	**Affected Yes/No**	**Rationale**
Characteristics			inventoried in the late 1970s (0407-01, Dry Gulch; 0406-07, Lone Pine Peak; and 0406-09, Bradbury Flat), and three of the units were first inventoried for the purposes of this project (0406-16, Gossi Spring; 0406-17, Broken Wagon; and 0406-15, Warm Springs). These units are located on the flats and foothills west of Highway 93 between the town of Challis and Trail Creek Road. The units are primarily composed of low-lying vegetation (grasses and sagebrush) with some of the steeper, higher elevation slopes hosting mahogany and evergreen stands. With the exception of a portion of Unit 0406-07, all were found to be clearly and obviously lacking wilderness characteristics when initially inventoried in 1979. During re-inventory in 2012 it was found that this continues to be the case. The portion of Unit 0406-07 not found to be clearly and obviously lacking wilderness characteristics during initial inventory (identified as unit 46-7) was not evaluated further in the 1980 Idaho Intensive Wilderness Inventory Proposed Decision. However, during re-inventory in 2012 it was determined that this area does not have outstanding opportunities for either solitude or primitive and unconfined recreation. Therefore, there are no Lands with Wilderness Characteristics present or affected within the project area.
Migratory Birds	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Mineral Resources	**Yes**	**No**	There are mineral resources (e.g., material that could be used as fill) in essentially all of the Challis Field Office area, including the project area. However, there would be no meaningful affects to such resources from the Proposed Action or alternatives.
Native American Religious Concerns	**Yes**	**No**	There are no known ceremonial sites or resources associated with ceremonial practices in the proposed project area.
Paleontological Resources	**No**	**No**	There are no known paleontological resources located in the proposed project area.
Range Resources	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Recreational Use	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Socio-economics	**Yes**	**Yes**	The proposed action is consistent with the prevalent economic and social values characteristic of this area. Many of the permittees within the CHMA are running far below permitted use in part due to the high

Table 3. Resources Considered in Impact Analysis			
Resource	**Present Yes/No**	**Affected Yes/No**	**Rationale**
			numbers of horses. With lower horse numbers they may be able run more livestock and add economic growth to Custer County. It is not known if there is revenue generated from Wild Horse viewing. If there is it may be temporarily reduced by fewer horses available. Impacts are disclosed under Environmental Effects.
Soils	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Threatened, Endangered, and Sensitive Fish; Fisheries	**Yes**	**Yes**	There is an absence of threatened / endangered fish or habitat throughout most of the CHMA. Where fisheries resources occur in the Road Creek watershed, and limited gather activities would also occur, measures are included in the action alternatives to prevent effects fish, stream channel habitat, or adjacent riparian areas. The distribution of fish and designated critical habitat along with description of activities and elements intended to prevent effects are disclosed under Affected Environment and Environmental Effects.
Threatened, Endangered, and Sensitive Animals	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Threatened, Endangered, and Sensitive Plants	**Yes**	**No**	There are 5 sensitive plant species found within the proposed project area. They are: Lemhi Milkvetch (*Astragalus aquilonius*), Challis Crazyweed (*Oxytropis besseyi* var. *salmonensis*), Wavy-Leaf Thelypody (*Thelypodium repandum*), Park Milkvetch (*Astragalus leptaleus*), and Challis Milkvetch (*Astragalus amblytropis*). No capture sites would be located within known plant populations. Capture sites not previously surveyed would be surveyed prior to gather site construction.
Tribal Treaty Rights and Interests	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Vegetation	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Visual Resources	**Yes**	**No**	All facilities would be temporary and be removed at the conclusion of the action.
Wastes, Hazardous and Solid	**Yes**	**No**	Hazardous material (DVM drugs (including PZP22) and liquid Nitrogen) in use during the gather operation would be kept, used and disposed of under the supervision of trained BLM staff, contract DVM or APHIS DVM.
Water Quality (Surface and Ground)	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Wetland and Riparian Zones	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.

Table 3. Resources Considered in Impact Analysis			
Resource	**Present Yes/No**	**Affected Yes/No**	**Rationale**
Wild and Scenic Rivers	**No**	**No**	There are no known Wild and Scenic Rivers in the area.
Wildlife	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Wild Horses	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.
Wilderness	**Yes**	**Yes**	Impacts are disclosed under Environmental Effects.

3.1 General Description of the Affected Environment

The CHMA encompasses 154,150 acres of BLM, 9,454 State of Idaho and 1,116 private lands near the East Fork of the Salmon River. The herd area is bordered on the north by the Salmon River, on the west by the East Fork of the Salmon River, on the south by the ridgeline between Herd Creek and Road Creek and on the east by U.S. Highway 93 and the watershed boundary between the Salmon River drainage and the Lost River drainage.

The climate of the region is semi-arid high desert typical of the Rocky Mountains in central Idaho. This climate is characterized by cold winters and hot dry summers which are affected by the Pacific Ocean maritime masses. Elevations, topography and aspect result in high variability in microclimates throughout the CHMA. The nearest national weather service station is located in Stanley, Idaho (1916-2010). This site recorded a mean monthly rainfall of 1.62 inches during January and 0.59 inches during July. Mean monthly max temperatures were 26.5°F in January and 78.5°F in July. The total annual precipitation varies with elevation as a result of orographic lifting resulting in 20-30 in (based upon Snotel Data from Mill Creek Summit site 627 at 8800 feet amsl) of annual precipitation near mountain tops and as little as approximately 7 inches of annual precipitation occurring on the valley floor. Most of the precipitation in the valley occurs as snow at higher elevations during fall and winter months.

The upland vegetation of the East Fork Watershed is dominated by coniferous forests with deciduous wooded areas interspersed along the watercourses. Highly productive mixed conifer stands at low to middle elevations consisting mainly of Douglas-fir, and lodgepole pine. At higher elevations, the moderately productive conifer species are Engleman spruce, subalpine fir, and lodgepole pine. Understory vegetation in the forested areas consists of various shrubs, forbs and grasses. Drier areas support grassland vegetation on sites where trees are scattered or absent. These lower elevation lands consist of a sagebrush/grass complex. Varieties of sagebrush (Artemesia spp.) dominate the watershed below 16 inches of annual precipitation. Mixed salt shrub types (Atriplex spp) are also present below 10 inches of annual precipitation. Herbaceous understory generally includes bluebunch wheatgrass, blue grasses, Idaho fescue, needle grasses, squirreltail, and a variety of perennial and annual forbs.

3.2 Wild Horses

3.2.1 Affected Environment

Congress passed the Wild Free Roaming Horses and Burros Act (WFRHBA) in 1971. The Act recognized the value of wild horses and burros on public lands, and directed public lands management agencies, including BLM, to establish herd management areas where wild horses

and burros could be part of a thriving ecological balance. Within herd management areas, BLM establishes "Appropriate Management Levels" (or AMLs), which is a wild horse and burro population range that can be accommodated within the herd management area without adversely affecting other resources.

Since the passage of the WFRHBA, management knowledge regarding wild horse population levels has increased. By law, BLM is required to remove excess animals once a determination has been made that excess animals are present and removal is necessary. In the past 2 decades, program goals have shifted beyond establishing appropriate management levels for individual herds and conducting gathers to achieve and maintain wild horse populations within the established AML. Management actions resulting from shifting the program emphasis include increasing fertility control and adjusting sex ratios to reduce population growth rates, increased gather intervals, improving the accuracy of population inventories and collecting genetic baseline data to support genetic health assessments. Decreasing removal numbers while reducing population growth rates and ensuring the welfare of wild horses on the range is pertinent to these program goals.

The CHMA has been gathered 14 times since October 1979. Approximately 2000 horses have been gathered since that time. One hundred eighty five wild horses would remain in the CHMA after the gather; of these, about 55 would be mares treated with PZP-22 or latest formula and about 111 would be stallions or geldings; maintaining the sex ratio to 60:40 in favor of males to slow population growth rates and assist in maintaining wild horse population levels consistent with the established AML. The proposed gather would occur in October/November and would be conducted in accordance with the Gather Plan and Standard Operating Procedures (SOPs) located in Appendices A and B. Map 8 displays the proposed gather area, capture sites, wild horse winter range, livestock grazing allotments and pastures.

Wild horses have a long life-span (20-30 years), adapt well to a variety of habitats, and have few natural predators. They also reproduce at a prolific rate; 15-20% (17% in the CHMA) annual reproduction rates are not unusual. Consequently, it is very difficult to maintain the appropriate management level through natural means. Over the years, the BLM has attempted a variety of management techniques to control wild horse and burro populations. The most common method is removal of excess horses, with the intent that the horses would be adopted and trained for domestic use. However, interest in adoptions has declined in recent years, primarily because of the cost of care. Therefore, horses and burros that are removed from the range are often transported to holding facilities, where they are cared for until they are adopted or die. Currently, there are approximately 48,000 horses in short-term corrals and long-term holding facilities.

Long-term holding facilities are expensive to operate and, in the view of wild horse and burro advocates, are contrary to the purpose of the WFRHBA. In response to sky-rocketing costs and public sentiment, the BLM has focused on other methods of population control, including the injection of contraceptives in mares, and adjusting male-female ratios. The most common equine contraceptive used, PZP is effective for two-to-three years, and must be re-applied to maintain effectiveness. Similarly, male-female ratios change over time. Thus, while

contraceptive use and manipulation of the male-female ratio tends to reduce the reproductive rate, it does not preclude the need to periodically remove excess horses from the HMA.

The wild horses in the herd management area are descendants of domestic horses that were released into the wild in the 1800s and early 1900s. For many years, local residents captured the wild horses and bred them with a variety of stock. Presently, the Challis wild horses are a mixture of draft (primarily Percheron) and American Saddle types. This lineage explains the significant number of gray horses in the herd, although there are a variety of colors, including buckskin, sorrel, appaloosa, pinto and bay. Adult horses in the Challis wild horse herd weigh an average of 1,000 pounds and stand between 14.2 and 15.2 hands, with some individuals weighing over 1,200 pounds. The herd is generally healthy, with good genetic diversity. Herd size has varied over the years, primarily as a result of horses being gathered from the range.

Oral history provided by local ranchers was submitted in a court document dated April 15, 1980 (Thomas, 1980) and related that Morgan mares escaped from a ranch and were never recaptured while other Morgans were released, with no attempt to recapture. James Bennett's grandfather released good stallions on the range gathering the offspring each year. Some good saddle horses were also lost and never recovered. Tom Chivers stated that his grandfather ran range mares that were then bred to Shire and Belgian stallions (imported from England), as well as light saddle horses and coach horses. Lawrence Bradbury's grandfather had two or three French Coach Stallions that were turned loose on the range to breed horses for stagecoach horses. Pat Lynch raised both saddle and draft horses, letting the mares run on the range gathering the young draft horses as three year olds to halter brake and then gather again as 5 year olds to sell as teams. Joe Anderson raised saddle stock and catered to the Calvary remount program which added Thoroughbred genetics. One outstanding Thoroughbred or Standardbred stallion named Bally Hall was turned out on the range between the years 1910-1915. Kenneth (Kenny) Bradshaw's father raised Percheron and Belgian horses for his teams (he made his living as a freight driver), pasturing many of his horses on the range. Ken also remembered some good American Saddlers and Hambletonians that were later added to the range herds (Thomas 1980). In summary the CHMA is made up of Percherons, Belgians and Shires and a mix of light breeds. This lineage explains the significant number of gray horses in the CHMA.

Past gather results are listed in Table 4. Previous to and including 2002 all gathers in the CHMA were a "gate cut" action whereby the removal of animals stopped when the target number was reached. In 2004 and 2009 BLM's selective removal criteria was implemented. In 2004, 26 mares were treated with the fertility control PZP. Forty-three mares were treated and released as part of the 2009 gather and PZP treatment. A total of 1,775 horses have been removed since 1979 as part of 14 previous gathers.

Table 4. Challis Historical Gather Schedule

Date	Captured	Removed	Released	Died/Euthanized
Oct-79	148	148	0	0
Oct-80	307	306	1	0
Oct-83	311	311	0	0

Aug-02	106	95	11	0
Aug-04	140	86	51	1
July-09	366	141	167	2
Total	2119			

Forage is allocated for 185 horses or 2,220 Animal Unit Months (AUMs) in the CHMA. Monitoring data indicate that when the total horse population begins to reach the upper limit of 253 animals (3,036 AUMs), resource conditions begin to decline, especially in riparian areas. Winter Range is the limiting factor for the CHMA so AUMs are based on available forage in winter.

The first BLM population survey flight in 1971 counted 150 horses in the CHMA which helped to establish the original AML of 150 wild horses. In 1979 final grazing EIS and the CHMAP were completed. These decisions called for the "*horse population to average 162 animals with a sex ratio of 60% males to females to allow for no greater than 15% annual population increase*." On March 2, 1983 a Consent Judgment allowed the AML to fluctuate between 185-340 animals but allowed that "*levels may be adjusted, based on either monitoring evaluations, studies, any applicable land use plans or amendments, or upon the advice and recommendation of the Challis Experimental Stewardship Program (ESP) Steering committee. The 340 was based on maximum amount of winter forage available.*" (USDI-BLM 1989). On July 1, 1987 the ESP steering group concerned about heavy winter snows and spring range not being ready to be grazed by large numbers of animals determined to manage the herd numbers at a level of 185 horses. The 1989 CHMAP Revision upheld this number as does the 1999 Challis RMP. The 1999 RMP also recognized that while the AML is 185 that the wild horse population would increase to 253 between gathers.

Wild horses are a long-lived species with documented survival rates ranging between 92% and 95% for all age classes and do not have the ability to self-regulate their population size.

Table 5. Herd Management Areas' Age/Sex and Survival Rates used in WinEquus Modeling.

Wild Horse Range	Age/Sex Classes	Survival Rate
Pryor Mountain Wild Horse Range, Montana	Foal	>95%
	15 years and younger, except for foals, both sexes	93%
Granite Range HMA, Nevada	Foal	>95%
	15 years and younger, except for male foals	92%
Garfield Flat HMA, Nevada	Foal	> 95%
	24 years and younger, except both foals, both sexes	92%

Ecological carrying capacity of a population refers to the level at which density-dependent, population regulatory mechanisms would take effect within the herd. At that level, the herd would show obvious signs of ill fitness. These include poor individual animal condition, low birth rates, and high mortality rates in all age classes due to disease and/or increased vulnerability to predation. Predation and disease have not substantially regulated wild horse population levels within the proposed gather area. Wild horses in general are very resilient and adaptable animals that are able to survive in poor quality habitat. Wild horses typically do not begin to show signs of body condition decline until the habitat components are severely deficient. Once the decline begins, their health deteriorates rapidly.

Baseline genetic diversity and viability samples were gathered in 2002. A total of 46 blood samples were taken during the 2002 gather to create baseline data to establish the current level of genetic diversity for the CHMA. A summary of the data indicates the following:

- The total number of genetic variants was about what is average for domestic horse breeds and well above normal for wild horse populations.
- Genetic variation is well above mean values seen for wild herds and domestic breeds.
- Genetic similarity. The highest mean *(S*) was with the New World Spanish breeds, followed closely by North American Gaited breeds. However, a dendrogram of genetic similarity of the Challis herd to domestic breeds placed the Challis herd within the cluster of the Heavy Draft and True Pony breeds. This likely indicates a mixed breed origin for the herd which also accounts for the high variability and high proportion of rare alleles.
- Variation in the Challis herd is fairly high, most likely due to a mixed breed origin of the herd and a relatively high recent population size.
- The Challis herd is a single interbreeding group.
- No action to modify the genetic makeup of the herd was recommended at the time of the analysis (2003). Of most importance is that Dr. Cothran stated of the CHMA under the recommendation's heading that "*The **AML is high enough that no action should be required** for many generations unless there is a catastrophic reduction in population size.*" (Genetic Analysis of the Challis feral horse herd p.4 emphasis added)

Population Modeling Summary

The Wild Horse Population Model (*WinEqqus version 1.40*) developed by Dr. Steve Jenkins was used to estimate the population growth and size of herds five years after the gather. Dean Bolstad, Washington Office Wild Horse and Burro Specialist, stated "*We recognize that some of the data in the model may not be exact for any given herd management area, but the model has been useful to approximate the effects of management actions and to compare alternatives*". (Bolstad personal communication 2009).

Population modeling was completed for the proposed action and alternatives (Table 6) to analyze how the alternatives would affect wild horse populations. The primary objective of modeling was to identify if any of the alternatives crash the population or cause extremely low population numbers or growth rates. Modeling included: Alternative 1 removal of excess wild horses with implementation of fertility control and maintaining the sex ratio; Alternative 2 removal only; and Alternative 5 No Action (no removal) where any management on the CHMA would be delayed for a 10 year period. The adaptations in the population described by Alternatives 3 and 4 are not an available option in the model. It may be assumed that Alternative 3 numbers would range slightly lower than Alternative 1 and that Alternative 4 numbers would range higher than Alternative 1. The results of population modeling show that minimum population levels and growth rates would be within reasonable levels and adverse impacts to the population would not be likely under Alternatives 1 and 2. Graphic and tabular results are displayed in detail in Appendix D. The population model is run for a period of 11 years including the current year. In other words it is the current year and a 10 year period.

Table 6. Alternatives Modeled in WinEquus

Alternative	Number Gathered (11 years)*	Number Removed (11years)*	Number treated	Median Growth Rate Next 10 Years (%)	Projected Gather (Year)	Average population (11 Years)
Alternative 1 Proposed Action	658	344		12.2%	2022	192
Alternative 2 Removal Only	735		171	15.8%	2022	210
Alternative 5 No Action	N/A	N/A	N/A	15.5%	2022	512

* The WinEquus model runs analysis for 11 years including the current year so that it projects the information for the following 10 years.

3.2.2 Environmental Effects—Wild Horses

Impacts to wild horses would occur on either the individual or the population as a whole. Direct impacts include stress or injuries associated with gathering, sorting, and handling of animals. Indirect impacts include changes in herd dynamics or population numbers.

Proposed Action -Removal, Fertility Control, Maintain Sex Ratio, and Remote Darting

Individual animals would experience moderate levels of physical and psychological stress for short periods of time during gather operations. Heart rates would be elevated, especially during

the final move into a trap site. However, animals would be moving at a walk/trot during most of the gather and would not be moving more than 8-10 miles with the majority traveling 5 - 6 miles. While wild horses in the CHMA are habituated to low levels of human activity (recreation and livestock management) higher levels of disturbance related to gather operations could cause anxiety in individuals. Because all phases of the process would be carried out according to BLM policy, individual stress would be minimized. Animals would be expected to recover from stress within 24 hours of entering the capture site.

Helicopter pilots allow wild horses to travel at their own pace for most of the distance to the gather location. The pilots are very experienced and do not excessively pressure the horses until the horses enter the wings of the capture site, when it is important to move the horses safely into the capture site and prevent them from turning back or trying to disband at the last minute. This is to avoid the need to re-gather or to rope the horses from horseback which could expose them to additional stress or injury. Foals separated during the gather process are safely grouped and transported to the sorting/holding facility to be reunited with their mother.

BLM staff would coordinate with the contractor on a daily basis to determine animal locations in proximity to gather sites, and to discuss terrain, animal health, gather distances and other gather logistics to ensure animal health and safety. Injuries would be examined and treated if needed by a veterinarian at the sorting/holding corrals.

Transport and sorting is completed as quickly and safely as possible so as to move the horses into the large holding pens where they can settle in with hay and water. When releasing animals back to the range, they would be returned to the same general area from which they were gathered.

The BLM has been gathering excess wild horses from public lands since 1975, and using helicopter since the late 1970s. Refer to Appendix B for information about methods that are utilized to reduce injury or stress to wild horses and burros during gathers. The national average mortality rate is 0.5%. In the CHMA 2009 gather, out of 366 horses gathered the mortality rate averaged 0.5% which is very low when handling wild animals. Another 0.6% of the animals captured were humanely euthanized due to pre-existing conditions and in accordance with BLM policy number WO-IM-2009-041. Another 2% died or were euthanized while in short term holding due to liver failure, injuries caused by other horses or collisions with corrals. This data affirms that the use of helicopters and motorized vehicles has proven to be a safe, humane, effective and practical means for the gather and removal of excess wild horses from the range. BLM staff is on-site at all times to observe the gather, monitor animal health, and coordinate the gather activities with the contractor. The SOPs outlined in Appendix B would be implemented to ensure that the gather is conducted in a safe and humane manner, and to minimize potential impacts to or injury of the wild horses. In their August 2012 BLM Task Force Report, the AAEP concluded that the care, handling and management practices utilized by the agency are appropriate for the horses and generally support the safety, health status and welfare of the animals.

Over the past 35 years, various impacts to wild horses from gathers have been observed. Individual, direct impacts to wild horses include handling stress associated with the capture,

sorting, animal handling, and transportation of the animals. The intensity of these impacts varies by individual, and is indicated by behaviors ranging from nervous agitation to physical distress. Observations made through completion of gathers show that the majority of wild horses captured acclimate quickly to the sorting/holding facility situation, becoming accustomed to water tanks and hay, as well as human presence. Both the BLM Wild Horse and Burro Specialists, and the Gather Contractor and crew are very attentive to the needs of all wild horses captured during gathers, ensuring their health and safety.

Accidental death or the need to humanely euthanize animals, as a direct result of gather activities is infrequent and averages less than one half to one percent (0.5 -1%) of the wild horses gather. Injuries sustained by wild horses during gathers may include nicks and scrapes to legs, face, or body from brush or tree limbs while being herded to the capture sites by the helicopter. Rarely, wild horses would encounter barbed wire fences and would receive wire cuts. These injuries are generally not fatal and are treated with medical spray at the sorting/holding corrals until a veterinarian can examine the animal. During some gathers, due to temperament and/or body condition, injures are more frequent, while on other gathers no wild horses are injured or die.

Most injuries are sustained once the animal has been captured and is either within the capture sites, sorting/holding facility, or occurs during sorting. These injuries result from kicks and bites or from collisions with corral panels or gates. Transport and sorting is completed as quickly and safely as possible to reduce the occurrence of fighting and then the wild horses are moved into large holding pens to settle in with hay and water. Injuries received during transport and sorting most often consist of superficial wounds of the rump, face, or legs. Occasionally, horses may sustain a spinal injury or a fractured limb which requires humane euthanasia but these injuries are rare. Similar injuries could be sustained if wild horses were captured through water or bait trapping, as the animals still need to be sorted, aged, transported, and otherwise handled following their capture.

Indirect individual impacts are those impacts which occur to individual horses after the initial stress event, and may include spontaneous abortions in mares, and increased social displacement and conflict in stallions. These impacts, like direct individual impacts, are known to occur intermittently during wild horse gather operations. An example of an indirect individual impact would be the brief skirmish which occurs amongst older stallions following sorting and release into the stud pen. Traumatic injuries usually do not result from these conflicts.

Spontaneous abortion events among mares following capture is very rare. Observations following capture indicate the rate of miscarriage varies, but can occur in about 1 to 5% of the captured mares, particularly if the mares are in very thin body condition or in poor health. This is not likely to be a significant factor based on the timing of this gather and the healthy state of horses in the CHMA.

Stallions selected for release would be released to increase the post-gather sex ratio to approximately 60% stallions in the remaining herds. Stallions would be selected to maintain a diverse age structure, herd characteristics and body type (conformation). It is expected that releasing additional stallions to reach the targeted sex ratio of 60% males would result in smaller band sizes, larger bachelor groups, and some increased competition for mares. With more

stallions involved in breeding it should result in increased genetic exchange and improvement of genetic health within the herd.

Through the capture and sorting process, wild horses are examined for health, injury and other defects. BLM Washington Office Instruction Memorandum IM-2009-041 is used as a guide to determine if animals should be euthanized (refer to SOPs Appendix B). Animals that are euthanized for non-gather related reasons include those with old injuries (broken hip, leg) that have caused the animal to suffer from pain or prevents them from being able to travel or maintain adequate body condition; old animals that have lived a successful life on the range, but now have few teeth remaining, are in poor body condition, or are weak from old age; and wild horses that have congenital, hereditary, or serious physical defects such as club foot or sway back.

It is expected that a few foals may be orphaned during a gather. This can occur if the mare rejects the foal, the foal becomes separated from its mare and cannot be matched up following sorting, the mare dies or must be humanely euthanized during the gather, the foal is ill or weak and needs immediate care that requires removal from the mare, or the mare does not produce enough milk to support the foal. On occasion, foals are gathered that were previously orphaned on the range (prior to the gather) because the mother rejected it or died. These foals are usually in poor condition. Every effort is made to provide appropriate care to all horses, including orphaned foals. BLM staff or DVMs may administer electrolyte solutions or orphan foals may be fed milk replacer as needed to support their nutritional needs. Orphan foals may be placed in a foster home in order to receive additional care. Despite these efforts, some orphan foals may die or be humanely euthanized as an act of mercy if the prognosis for survival is very poor. Due to the timing of the proposed gather, it is unlikely that orphan foals would be encountered as the majority of the current year‘s foals would be weaned already from their mothers.

Wild horses are usually very fit and in good health when not stressed by lack of food and water and are able to endure the physical requirements of a gather. However, the environmental conditions and the overall health and well-being of the wild horses is continually monitored through both summer and winter gathers to adjust gather operations as necessary to protect the wild horses from gather-related health issues. For these reasons, flexibility in gather operations is an inherent part of all gathers.

Wild horses in the CHMA often use snow instead of water when available during fall, winter, and spring months. Wild horses in the CHMA have easy access to water so horses are well hydrated when moving to capture sites. In any case, wild horses are typically in top physical fitness and are able to endure the physical demands of a gather (whether in winter or summer) better than most domestic horses that are not on a top physical training routine due to the requirements of surviving in the wild. Most temperature related issues during a gather can be mitigated by adjusting daily gather times to avoid the extreme hot or cold periods of the day.

Snow accumulation may occur in October, which can increase fatigue and stress. The helicopter pilot, regardless of season, allows horses to travel slowly at their own pace. The Contractor may stomp trails in the snow leading to the capture sites to make it easier for horses to travel to the gather site.

BLM does not gather wild horses with a helicopter unless it is an emergency during the six weeks before or after the *peak* foaling period (April and mid-May) which correlates to the 4 month period between March 1 and June 30 when a majority of foals are born. It is not uncommon for a very small number of foals to be encountered during any month of the year; however most are born during March thru June. If newborn foals or foals too young to wean are gathered, they are matched up with their mares after being gathered. During the proposed gather, most foals would be 5-7 months old and of bigger body size, and can be weaned, if they have not been weaned naturally already. Fall and winter time-frames are less stressful to foals than summer gathers due to them being older and more self-sufficient. Young foals in summer months may be more prone to dehydration and complications from heat stress. Additionally, handling, sorting and transport can be a stress to young animals however, BLM staff on site takes every precaution to assure that horses are handled and maintained to reduce these concerns.

Removal of excess wild horses would improve herd health. Decreased competition for forage and water resources would reduce stress and promote healthier animals. Implementation of Alternative 1 would allow for healthy range conditions and animals over the long term. Reduced population growth rates would be expected to: extend the time until AML is exceeded; increase the intervals between gathers; reduce disturbance to individual animals and herd social structure over the foreseeable future. Modeling suggests that average population growth rates under the median trial for the Proposed Action would be 6.1%. Gathers would still need to occur every 3 years in order to re-apply fertility control, however, according to the modeling, Alternatives 1 and 3 would remove 289-560 fewer wild horses over 11 years.

According to the modeling, if follow-up gathers could be implemented on a regular basis, population control measures may be adequate to maintain the population within existing AMLs.

Population Growth Controls (Fertility Control treatments and sex ratio adjustments)

Under the Proposed Action and Alternatives 3 and 4, the objective for the gather would include the application of fertility control to approximately 55 mares which would be released. All mares selected for release would be treated with a single dose of two-year PZP-22 or similar vaccine/fertility control. Immuno-contraceptive (fertility control) treatments would be conducted in accordance with the approved standard operating procedures (SOPs, Appendix B). Mares selected for release would be selected to maintain a diverse age structure, herd characteristics and conformation (body type).

When injected, PZP (antigen) causes the mare‘s immune system to produce antibodies; these antibodies bind to the mare‘s eggs and effectively block sperm binding and fertilization (Zoo Montana, 2000). PZP is relatively inexpensive, meets BLM requirements for safety to mares and the environment, and can easily be administered in the field. In addition, among mares, PZP contraception appears to be completely reversible. The vaccine has also proven to have no apparent effect on pregnancies in progress, the health of offspring, or the behavior of treated mares (Turner et. al, 1997). Available data from 20 years of application to wild horses contradicts the claim that PZP application in wild mares causes mares to foal out of season or late in the year (Kirkpatrick and Turner 2003). The PZP vaccine is currently being used on over 75 horse management areas for the BLM and its use is appropriate for all free-ranging wild horse

herds. The long-term goal is to reduce or eliminate the need for gathers and removals (Kirkpatrick et al. 2010).

The highest success obtained for fertility control has been achieved when applied during the timeframe of November through February. Efficacy for application of the two-year PZP vaccine based on winter application is as follows:

Table 7. Fertility Control Effectiveness				
	Year 1	**Year 2**	**Year 3**	**Year 4**
Winter Period	Normal	94%	82%	68%
Summer Period	Normal	80%	65%	50%

The treatment would be controlled, handled, and administered by a trained BLM employee (Fertility SOPs, Appendix B). Mares receiving the vaccine would experience slightly increased stress levels associated with handling while being vaccinated and freeze-marked. Serious injection site reactions associated with fertility control treatments are rare in treated mares. Any direct impacts associated with fertility control, such as swelling or local reactions at the injection site, would be minor in nature and of short duration. Most mares recover quickly once released back to the CHMA, and none are expected to have long term impact from the fertility control injections.

As the sole approach, contraception would not allow the BLM to achieve the original population objectives; however, in conjunction with other techniques (e.g., removals of excess animals and adoption) and through incorporation of other population control techniques (e.g., sex ratio adjustments), it now provides a valuable tool in a larger, adaptive management approach to wild horse and burro management.

Contraception may be a cost effective and humane treatment to employ in horses to prevent increases in populations, or with other techniques, to reduce horse populations (Bartholow 2007). In general, contraception would not remove horses from an CHMA‘s population which would result in some continuing environmental effects by those individuals. Horses are long-lived reaching 20 or more years of age in the wild and those horses returned to the CHMA may continue exerting throughout their life span negative effects on the environment as described above, as opposed to the removal of a horse. Contraception, if effective, reduces future reproduction. Limiting future population increases of horses would limit increases in environmental damage from higher densities of horses. It may also reduce the effect of horse gather activities on the environment (if it limits the numbers of horse gathers required). If application of contraception to horses requires capturing and handling horses, the risks and costs associated with capture and handling of horses may be roughly equivalent (not counting the cost of adoption). Application of contraception to older animals and returning them to the CHMA may reduce risks associated with horses that are difficult to adopt or handle in captivity.

Ransom et al. (2010) found no differences in how PZP-treated and control mares allocated their time between feeding, resting, travel, maintenance, and social behaviors in three populations of wild horses, which is consistent with Powell (1999) findings in another population. Likewise, body condition of PZP-treated and control mares did not differ between treatment groups in

Ransom et al's (2010) study. Turner and Kirkpatrick (2002) found that PZP-treated mares had higher body condition than control mares in another population, presumably because energy expenditure was reduced by the absence of pregnancy and lactation.

In two studies involving a total of four wild horse populations, both Nunez et al. (2009) and Ransom et al. (2010), found that PZP-treated mares were involved in reproductive interactions with stallions more often than control mares, which is not surprising given the evidence that PZP-treated females of other mammal species can regularly demonstrate estrus behavior while contracepted (Shumake and Wilhelm 1995, Heilmann et al. 1998, Curtis et al. 2002). Ransom et al. (2010) found that control mares were herded by stallions more frequently than PZP-treated mares, and Nunez et al. (2009) found that PZP-treated mares exhibited higher infidelity to their band stallion during the non-breeding season than control mares. Madosky et al. (in press) found this infidelity was also evident during the breeding season in the same population that Nunez et al. (2009) studied, resulting in PZP-treated mares changing bands more frequently than control mares. Long-term implications of these changes in social behavior are currently unknown. Kirkpatrick et al. (2010) conclude by stating that the larger question is, even if subtle alterations in behavior may occur, this is still far better than the alternative and that the other victory for horses is that every mare prevented from being removed, by virtue of contraception, is a mare that would only be delaying her reproduction rather than being eliminated permanently from the range. This preserves herd genetics, while gathers and adoption do not. (Kirkpatrick and Turner 2002, 2008; Turner and Kirkpatrick 2002, 2003; Willis et al. 1994.) Population wide indirect impacts are more difficult to quantify and would occur over time. A large percentage of inoculated mares would experience reductions in fertility. Recruitment of foals into the population would be reduced over a three-year period. The potential multi-year reprieve from foaling would greatly increase overall health and fitness of the mares, as well as the health of the foals born after fertility returns.

Following resumption of fertility, the proportion of mares that conceive and foal could be increased (rebound effect) due to the increased fitness. Additionally, fertility control treatment could cause breeding and foaling seasons to become out of sync with foals born earlier or later in the year, or throughout the year but is generally associated with the timing of the treatment and not the vaccine itself. Research is continuing to document and quantify these effects.

The indirect effect of fertility control and adjustment of sex ratios to favor stallions would extend the time before another gather is required when compared to a gather without implementation of either population growth control method. Wild horses would experience reduced stress and disruption to population dynamics as a result of less frequent gathers. However, it is being recommended that the BLM return to these areas every 2-3 years to re-apply fertility control in order to maintain its effectiveness in controlling population growth rates. By reducing population growth rates, the number of wild horses that would have to be removed from the CHMA during future gathers would also be reduced or possibly eliminated.

Fertility control application would allow the average population size to be maintained at a level consistent with the AML. Long term genetic and physical health and future reproductive success of mares within the herd would be sustained. Reduced population growth rates and smaller population sizes would also allow for improvements to range condition, which would have long-

term benefits to wild horse habitat quality and contribute to the achievement and maintenance of a thriving natural ecological balance.

Population control methods including the adjustment of sex ratios to favor stallions would be expected to have relatively minor impacts to overall population dynamics. Under the Proposed Action and Alternatives 3 and 4, impacts of additional stallions in the population could include: decreased band size, increased competition for mares, and increased size and number of bachelor bands. These effects would be slight, as the proposed sex ratio is not an extreme departure from normal sex ratio ranges. Conversely, a selection criterion, which leaves more mares than stallions, would be expected to result in fewer and smaller bachelor bands, increased reproduction on a proportional basis with the herd, and larger band sizes. With more stallions involved in breeding it should result in increased genetic exchange and improvement of genetic health within the herd.

Modification of sex ratios for a post-gather population favoring stallions is expected to reduce growth rates and subsequent population size, as a smaller proportion of the population would consist of mares that are capable of giving birth to foals. As a result, gather frequency could be reduced as well as the numbers of horses gathered and removed in future gathers.

Wild horses that are gathered would be subject to one or more of several scenarios listed below:

Wild Horses Remaining or Released into the CHMA following Gather

The post-gather goal would be for 185 wild horses to remain within the CHMA. Approximately 137 excess wild horses would be removed during the gather. Wild horses that are not captured may be temporarily disturbed and move into other areas during gather operations. With the exception of changes to herd demographics, direct population wide impacts have proven, over the last 33 years, to be temporary in nature and with most if not all impacts to individual wild horses disappearing within hours to several days of release. No observable effects associated with these impacts would be expected within one month of release except a heightened awareness of human presence.

Herd population dynamics, age structure or sex ratio, growth rates and population size over time are the primary attributes directly related to the proposed gather.

The National Selective Removal Criteria (Appendix B) would be followed to the extent possible, however it is expected that the majority of released and non-gathered animals would consist of all age groups greater than 5 years of age.

The effects of successive removals on populations causing shifts in herd demographics favoring younger horses (5 to 15 years) would also have direct effects on the population. These impacts are not thought of as adverse to a population. They include development of a population which is expected to be more biologically fit, more reproductively viable, and more capable of enduring stresses associated with traumatic natural and artificial events.

The genetic effective population size (Ne) is a measure of the total number of mares and stallions which contribute genetically to the next generation. A population with an age structure involving high numbers of young animals (<5 years of age) would have a lower value of Ne than a similar sized population with a larger component of older breeding-age animals (>5 years of age). Through implementation of the BLM selective removal policy, the wild horses aged 5-10 years of age would be the first priority for release back to the range. Most or all wild horses under five years of age would be removed, thus resulting in a potential increase to the Ne in the CHMA.

Temporary Sorting/Holding Facilities During Gathers

Wild horses gathered would be transported from the capture sites to a temporary sorting/holding facility within the CHMA, primarily in goose-neck trailers, however straight deck semi-trailers may be used. At the temporary sorting/holding facility wild horses would be aged and sorted into different pens based on sex, age and other variables. The horses would be fed certified weed free quality hay and fresh water while in the sorting/holding facility. Mares and their un-weaned foals (if encountered) would be kept in pens together and marked similarly for identification. Horses identified for retention in the CHMA and for fertility control treatment would be maintained in these temporary corrals until the fertility control treatment could be implemented and then be released back into the CHMA.

At the temporary sorting/holding facility recommendations to the BLM regarding care, treatment, and if necessary, euthanasia of the recently captured wild horses would be provided by a licensed DVM. Any animals affected by a chronic or incurable disease, injury, lameness or serious physical defect (such as severe tooth loss or wear, club foot, and other severe congenital abnormalities) would be humanely euthanized using methods acceptable to the American Veterinary Medical Association (AVMA) in accordance to WO-IM- 2009-041.

Transport, Short Term Holding, and Adoption Preparation

Wild horses removed from the range would be transported to the receiving short-term holding facility in a goose-neck stock trailer or straight-deck semi-tractor trailer. Trucks and trailers used to haul wild horses would be inspected prior to use to ensure they can be safely transported. Wild horses would be segregated by age and sex when possible and loaded into separate compartments. Mares and their un-weaned foals may be shipped together. Transportation of recently captured wild horses is limited to a maximum of 12 hours. During transport, potential impacts to individual horses can include stress, slipping, falling, kicking, biting, or being stepped on by another animal. Unless wild horses are in extremely poor condition, it is rare for an animal to die during transport.

Upon arrival, recently captured wild horses would be off-loaded by compartment and placed in holding pens where they would be provided good quality hay and water. Most wild horses begin to eat and drink immediately and adjust rapidly to their new situation. At the short-term holding facility a veterinarian would provide recommendations to the BLM regarding care, treatment, and if necessary, euthanasia of recently captured horses. Any animals affected by a chronic or incurable disease, injury, lameness or serious physical defect (such as severe tooth loss or wear, club foot, and other severe congenital abnormalities) would be humanely euthanized using methods acceptable to the AVMA. Wild horses in very thin condition or animals with injuries

would be sorted and placed in hospital pens, fed separately and/or treated for their injuries. Recently captured horses, generally mares, in very thin condition may have difficulty transitioning to feed. A small percentage of animals can die during this transition; however, some of these animals are in such poor condition that it is unlikely they would have survived if left on the range.

After the recently captured horses have transitioned to their new environment, they are prepared for adoption, sale, or transport to a long-term grassland pastures. Preparation involves freeze-marking the animals with a unique identification number, vaccination against common diseases, castration, and de-worming. During the preparation process, potential impacts to wild horses are similar to those that can occur during transport. Injury or mortality during the preparation process is rare, but can occur.

At short-term corral facilities, a minimum of 700 square feet is provided per animal. Mortality at short-term holding facilities averages approximately 5% (GAO-09-77, Page 51). This includes animals euthanized due to a pre-existing condition, animals in extremely poor condition, animals that are injured and would not recover, animals which are unable to transition to feed, and animals which die accidentally during sorting, handling, or preparation. Approximately 12,000 excess wild horses are being maintained within BLM's short-term holding facilities.

Adoption

Adoption applicants are required to have at least a 400 square foot corral with panels that are at least six feet tall. Applicants are required to provide adequate shelter, feed, and water. The BLM retains title to the horse for one year and the horse and facilities are inspected. After one year, the applicant may take title to the horse at which point the horse becomes the property of the applicant. Adoptions are conducted in accordance with 43 CFR § 5750.

Sale with Limitation

Buyers must fill out an application and be pre-approved before they may buy a wild horse. A sale-eligible wild horse is any animal that is more than 10 years old or has been offered unsuccessfully for adoption at least three times. The application also specifies that all buyers are not to sell to slaughter buyers or anyone who would sell the animals to a commercial processing plant. Sales of wild horses are conducted in accordance with the 1971 WFRHBA and congressional limitations.

Long-Term Grassland Pastures

Since fiscal year 2008, the BLM has removed over 31,680 excess wild horses or burros from the Western States. Most animals not immediately adopted or sold have been transported to long-term grassland pastures (LTP) in the Midwest.

Potential impacts to wild horses from transport to adoption, sale or LTP are similar to those previously described. One difference is that when shipping wild horses for adoption, sale or LTP, animals may be transported for up to a maximum of 24 hours. Immediately prior to transportation, and after every 24 hours of transportation, animals are offloaded and provided a minimum of 8 hours on-the-ground rest. During the rest period, each animal is provided access to unlimited amounts of clean water and two pounds of good quality hay per 100 pounds of body weight with adequate bunk space to allow all animals to eat at one time. The rest period may be

waived in situations where the anticipated travel time exceeds the 24-hour limit but the stress of offloading and reloading is likely to be greater than the stress involved in the additional period of uninterrupted travel.

Long-term grassland pastures are designed to provide excess wild horses with humane, and in some cases life-long care in a natural setting off the public rangelands. There, wild horses are maintained in grassland pastures large enough to allow free-roaming behavior and with the forage, water, and shelter necessary to sustain them in good condition. About 28,600 wild horses that are in excess of the current adoption or sale demand (because of age or other factors such as economic recession) are currently located on private land pastures in Oklahoma, Kansas, and South Dakota. Establishment of LTPs was subject to a separate NEPA and decision-making process. Located in mid or tall grass prairie regions of the United States, these LTPs are highly productive grasslands compared to more arid western rangelands. These pastures comprise about 256,000 acres (an average of about 10-11 acres per animal). Of the animals currently located in LTP, less than one percent is age 0-4 years, 49 percent are age 5-10 years, and about 51 percent are age 11+ years.

Mares and sterilized stallions (geldings) are segregated into separate pastures except at one facility where geldings and mares coexist. Although the animals are placed in LTP, they remain available for adoption or sale to qualified individuals; and foals born to pregnant mares in LTP are gathered and weaned when they reach about 8-12 months of age and are also made available for adoption. The LTP contracts specify the care that wild horses must receive to ensure they remain healthy and well-cared for. Handling by humans is minimized to the extent possible although regular on-the-ground observation by the LTP contractor and periodic counts of the wild horses to ascertain their well-being and safety are conducted by BLM personnel and/or veterinarians. A small percentage of the animals may be humanely euthanized if they are in very poor condition due to age or other factors. Horses residing on LTP facilities live longer, on the average, than wild horses residing on public rangelands, and the natural mortality of wild horses in LTP averages approximately 8% per year, but can be higher or lower depending on the average age of the horses pastured there (GAO-09-77, Page 52).

Euthanasia or Sale without Limitation

While euthanasia and sale without limitation has been limited by current Congressional appropriations, it is allowed under the WFRHBA. Neither option is available for horses under the Department of the Interior's fiscal year 2012 budgetary appropriations and is not expected to be available under the 2013 budgetary appropriations. Although the appropriations restrictions could be lifted in future appropriations bills, it would be contrary to Departmental policy to euthanize or sell without limitations to healthy excess wild horses.

Alternative 2: Removal Only

Gather methods are the same as described in Alternative 1.

Implementation of Alternative 2 would result in capturing fewer wild horses than would be captured in Alternative 1. Alternative 2 would not involve fertility control; mares would not undergo the additional stress of receiving fertility control injections or freeze-marking and would foal at normal rates until the next gather is conducted. The post-gather sex ratio would be about 60:40 stallions to mares with a small percentage of geldings from the 2009 gather. All other aspects of the wild horse gather would be the same as those described for Alternative 1.

Alternative 3: Removal with Fertility Control and Geldings Released as a Non Reproducing Component

Alternative 3 would involve fertility control; therefore, impacts related to fertility control would be the same as Alternative 1. The post-gather sex ratio would be 50:50 mares to stallions. This would be expected to result in fewer and smaller bachelor bands, increased reproduction on a proportional basis within the herd, larger band sizes, and individual mares would likely begin actively producing at a slightly older age.

Bands with a single stallion and mares with offspring would be expected to decline in both size and number while bachelor bands would increase in size and number. An increase in genetic diversity (heterozygosis [Ho]) may also occur within the CHMA with an increase in stallions. A greater number of smaller herds would allow more stallions a chance to express their genetics. These effects would be slight, as the proposed sex ratio is not an extreme departure from normal sex ratio ranges. Modification of sex ratios for a post-gather population favoring stallions or geldings would further reduce growth rates in combination with fertility control reducing the frequency of gathers. This is beneficial in reducing the fertility rate by adding a sterile component that is not reproducing. Field observations from geldings returned to the CHMA in 2009 have shown some geldings would express their stallion behavior; retaining mares and defending territories. Mares in bands held by geldings would not reproduce. All other aspects of the wild horse gather would be the same as those described for Alternative 1.

Alternative 4: Removal with Fertility Control without Sex Ratio Adjustment

Alternative 4 would involve fertility control; but would not include sex ratio alteration returning the sex ratio to 50:50 from the 60:40 stallions and geldings to mares after the 2009 gather. All other aspects of the wild horse gather would be the same as those described for Alternative 1.

Alternative 5: No Action (Deferred Gather)

Under the No Action Alternative, there would be no active management to control the population size within the established AML at this time. In the absence of a gather, wild horse populations would continue to grow at an average rate of 17% per year based on population inventories conducted within the CHMA. Without a gather and removal now, the population would grow to 1,630 in ten years based on the average annual growth rate.

Use by wild horses would continue to exceed the amount of forage allocated for their use. Competition between wildlife, livestock and wild horses would continue, particularly on winter range where quantity and quality of forage is the limiting factor. Damage to rangeland resources would continue or increase. Over time, the potential risks to the health of individual horses would increase, and the need for emergency removals to prevent their death from starvation would also increase.

Due to density dependent factors horses would disperse into less populated areas and outside the CHMA. Movement of wild horses into populated areas and on Highways 75 and 93 would create a public safety hazard. Auto/horse collisions would increase due to this dispersal. Over the long-term, the health and sustainability of the wild horse population is dependent upon achieving a thriving natural ecological balance and sustaining healthy rangelands. Allowing wild horses to die of starvation would be inhumane and would be contrary to the WFRHBA which requires that excess wild horses be immediately removed. Allowing rangeland damage to continue to result from wild horse overpopulation would also be contrary to the WFRHBA which requires the BLM to *protect the range from the deterioration associated with overpopulation, remove excess animals from the range so as to achieve appropriate management levels*, and *to preserve and maintain a thriving natural ecological balance and multiple-use relationship in that area*.

3.3 Vegetation Resources

3.3.1 Affected Environment

Forty-three upland vegetation communities have been identified within the Challis Field Office Area. All but four of these are found within the CHMA. The most dominate of these are sagebrush communities with varying understories of Idaho fescue (*Festuca idahoensis*), Bluebunch wheatgrass (*Pseudoroegneria spicata*), needle-and-threadgrass (*Hesperostipa comata*) or Sandbergs' bluegrass (*Poa secunda*) and Cusick's bluegrass (*Poa cusickii*) species. Five species of sagebrush are prevalent in CHMA those being Basin Big Sagebrush (*Artemisia tridentata tridentata*), Mountain Big Sagebrush (*Artemisia tridentata vaseyana*), Wyoming Big Sagebrush (*Artemisia tridentata Wyomingensis)*, Three Tip sagebrush (*Artemisia tripartita*) and Black Sagebrush (*Artemisia nova*). Also common are shadscale (*Atriplex confertifolia*) and chicken sage (*Sphaeromeria argentea*) communities with Swallen's needlegrass (*Achnatherum swallenii*), squirreltail (*Elymus elymoides*), and bluegrass understories on drier sites (<9 inch precipitation zones) and Douglas Fir (*Pseudotsuga menziesii*) and curled leaf mahogany (*Cercocarpus ledifolious*) communities on the higher elevation, wetter sites (>16" precipitation).

The upland communities are generally in a healthy state with adequate vegetative cover, good plant spacing, and relatively little invasion of noxious or invasive plants. Existing species composition (based on weight) places most of the sites in late seral stage. It is estimated that less than 30% of the CHMA is at mid to early seral stage.

There are 13 wild horse long term trend sites within the CHMA that were located in areas frequented by wild horses, but used infrequently by livestock due primarily to topography and/or distance to water. Seven of the Upland Trend study sites have been monitored in the last ten years and have applicable data. There are also 21 trend sites in Mountain Springs Allotment

within the CHMA, 4 on Bradbury Flat, 2 on Bradshaw Basin, 5 on Road Creek, 2 on Split Hoof, 5 on Warm Springs, and 1 in the Sand Hollow ACEC.

Table 8 below describes the ecological sites by study site and states trend and actual vs. expected vegetative cover. Only the studies that have been monitored in the last 10 years have been included in this analysis

*Total Ground Cover by Litter, Rock and Vegetation

3.3.2 Environmental Effects-Vegetation

Potential horse capture sites have been identified (Map 8), most of which have been used in the past; additional sites may be used, but would be selected to avoid sensitive resources (Appendix B).

Alternatives 1-4

Effects common to all alternatives except the "No Action".

Short-term disturbance would occur in the immediate vicinity of the capture sites and the loading chute. The soil would be compacted and vegetation would be trampled during panel installation by personnel and vehicles and severely trampled in the catch pen area by wild horses, domestic horses, and the wranglers. Crushing of standing vegetation would occur during gather activities from running horses. Previously used capture sites are visually unapparent and difficult to distinguish from adjacent areas. Native vegetation is typically restored in a single growing season with no sign of noxious or weedy species. Although roads and trails would be used where possible, certain impacts would occur. It is unlikely these impacts would result in significant numbers of plants affected or size of area affected. Large stature shrub communities in the wetter areas would experience minimal impacts, while the low stature shrub communities (chicken sage, fringed sage) occupying the drier, more fragile ranges may experience some mortality resulting in reduced ground cover and increased bare ground. Although these impacts may appear to be considerable on a site-specific basis, they are generally slight when viewed throughout the project area. The area may be seeded after the disturbance with a certified weed free native seed that is well suited for the site.

Many of the vegetation types occupying the Herd Management Area are dominated by bluebunch wheatgrass. This particular species is sensitive to grazing during certain times of its life cycle due to its growth form. When the growing points (apical meristems) reach grazing height (4-6 inches) the plant ceases all growth if it is grazed. This response may last several years depending upon the severity of grazing, climate year, and health of the plant affected. Nested frequency plots located within bluebunch wheatgrass communities throughout the CHMA have a trend as follows: 4 static sites, five upward trending sites, and seven downward trending sites. It has not been conclusively determined that the downward trending sites are a result of uncontrolled wild horse grazing or merely natural plant dynamics (i.e. responses to drought). By controlling wild horse numbers at a level anticipated to be in balance with ecological capabilities of the site, these bluebunch wheatgrass communities would remain healthy and vigorous. Vegetation would be impacted positively due to a decrease in herbivory. It would be expected that livestock numbers would not change despite the increased of vegetation. Many of the AUMs that are currently being unused may continue to be unused.

A very small percentage of vegetation would be affected by actual gather activities. Each capture site would disturb <1 acre of surface vegetation. Concentration areas of horses may extend out to < 5 acres. The sorting/holding facility may also disturb an additional five acres. There are typically 3-5 capture sites used each gather. Following this logic up to 10 acres or less than $1/10^{th}$ of 1% of the CHMA vegetation would be affected by alternatives 1-4.

Alternative 5: No Action, Deferred Removal (10 years)
This alternative would also allow for unrestricted increases in the number of horses in the CHMA. Ecological trend of upland sites across the CHMA would be expected to decline. Under Alternative 5, residual herbaceous cover and litter cover from native plants would decrease across the CHMA. During late fall, winter and early spring woody vegetation would be browsed. Utilization would be higher, plant vigor would be lower, plant mortality would be higher, and plant community shifts toward less palatable species would occur faster. Invasive

species would be expected to increase more rapidly, and special status plants habitat would be degraded.

3.4 Livestock Management

3.4.1 Affected Environment

The purpose of this section is to assess the potential direct and indirect effects to livestock management within the CHMA as a result of the Proposed Action and the Range of Alternatives. The information presented here is to supply the reader with a general background and degree of livestock use that occurs within the grazing allotments that occur within the CHMA.

Livestock grazing occurs on 88% of the CHMA; there are six cow/calf grazing allotments within the CHMA currently under deferred or deferred/rest rotation grazing systems with use periods of spring, summer and fall. Two additional areas (Malm Gulch and Sand Hollow) are closed to livestock grazing (Challis RMP, 1999a) due to fragile volcanic ash soils. Warm Springs, Mountain Springs, Road Creek, Split Hoof, Bradbury Flat and Bradshaw Basin allotments are within the CHMA. The pastures are relatively large and allow for a broad range of movement while livestock are present. Temporary electric fences are used to restrict livestock movement and to keep livestock out of the RHCA. Following the conclusion of the grazing season these temporary fences are disabled and gates are opened. The other primary resources associated with the rangeland environment include recreation activities, watershed protection, and wildlife habitat.

Actual use helps determine the current level of use and number of animals. Managers can then better balance the on the ground use with the numbers that are permitted onto public land. Actual Use is defined as "*means where, how many, what kind or classes of livestock graze on an allotment or on a portion or pasture of an allotment*" (43 CFR 4100.0-5). In 2011 49% of the allotted AUMs were permitted on BLM. Conversely, 51% of the available AUMs were not permitted for various reasons some of which are resource protection, numbers of wild horses, and range improvement maintenance. Table 9 below describes by allotment the percent of AUMs used and what percentage of the allotment falls within the CHMA.

Table 9. CHMA LIVESTOCK AUMS FOR THE 2011 BILLING CYCLE (March 1, 2011 to February 28, 2012)

Allotment	AUMs Available	Actual Use 2011	% of Use	% of Allotment in CHMA	Allotment Acres Within CHMA	% of CHMA
Bradbury Flat	839	273	33	100	15706	9
Bradshaw Basin	908	277	31	100	8184	5
Mt. Springs	8884	6688	77	59	55695	32
Frail Lands (unallotted)	0	0	0	100	19428	12

Table 9. CHMA LIVESTOCK AUMS FOR THE 2011 BILLING CYCLE (March 1, 2011 to February 28, 2012)						
Allotment	**AUMs Available**	**Actual Use 2011**	**% of Use**	**% of Allotment in CHMA**	**Allotment Acres Within CHMA**	**% of CHMA**
Road Creek	534	37	7	98	9933	6
Split Hoof	268	102	38	100	8520	5

Total	**16186**	**7964**	**49%**	**--**	**168648**	**100**

The CHMA has relatively few fences; most are "open ended" or drift fences that allow movement around the ends. There are some pasture fences that could limit travel. This is mitigated by gates being open except when livestock are present for 2-6 weeks during the year.

Table 10 below depicts the authorized livestock use (number of animals and dates of use) in the CHMA on all of the allotments except Mountain Springs which is depicted in Table 11.

**Outside CHMA, *Portion in CHMA, T- Trailing Action

There are also numerous range improvement projects located within the CHMA which have been built in cooperation with livestock operators in order to improve distribution of livestock, as well as conditions of the range. These projects include spring developments, stock ponds, vegetation treatments, water tanks, and guzzlers. Much of the maintenance of these projects, especially water developments is performed by livestock operators. Maintenance includes such actions as repair or replacement of pipelines and head boxes, and repair of water tanks. The construction and maintenance of these improvements benefit livestock, wild horses, and wildlife.

3.4.2 Environmental Effects—Livestock Management

Alternatives 1-4
Livestock may be present on the Warm Springs Allotment during gather. Because gates would be opened between allotments to facilitate movement of wild horses to capture sites, livestock could move between allotments during the gather. To prevent accidental trespass of livestock, permittees may be asked to move livestock to areas away from allotment boundaries or concentrations of wild horses. Livestock may experience some level of stress or may be displaced when the helicopter is in the area. This would put an additional burden on the livestock operator to ensure his cattle are out of the area. Impacts from humans and horses at capture site locations to livestock would be slight, localized per capture site, and for a limited period (<4 days).

Maintaining wild horse numbers within AMLs would result in slight reductions in forage utilization levels, around water developments, over a four year period. Overlap between wild horse and livestock use areas would also be limited resulting in appropriate utilization levels (40-50%) for each of the above allotments.

Alternative 5. No Action (Deferred Gather)
Increased horse numbers would result in increased competition for water and forage. This would result in vegetation utilization rates that would exceed the capacity of the area, degrading the forage resource and deteriorating the habitat. As the productivity and composition of desirable forage species decreases, an increase in the invasion of undesirable species would occur. This would result in greater competition for desirable forage between livestock and wild horses. It may also result in livestock traveling to more sensitive areas looking for more desirable forage. This decline would continue to the point that there would be both insufficient plant cover for range site protection and insufficient forage for all rangeland users, which in turn would reduce stocking rates and possible closure of the allotments. Livestock stocking rates may have to be reduced as wild horse population increases.

3.5 Invasive Species

3.5.1 Affected Environment
Invasive species and their encroachment on BLM administered lands represent a serious threat to the continued productivity, diversified use and aesthetic value of the CFO's public lands. BLM currently has an active noxious weed management program which emphasizes cooperation with Custer County, private landowners and BLM permitted land users. The CFO weed management program is based in part on the 2007 *Vegetation Treatments Using Herbicides on Bureau of*

Land Management Lands in 17 Western States Programmatic Environmental Impact Statement. (USDI-BLM, 2007), and the Challis-Salmon Field Office Integrated Weed Control Program, DOI-BLM-ID-330-2008-EA-30.

Under this integrated program, most known weed sites are inspected and treated on an annual basis. Use of herbicides has been evaluated by BLM in the *2007 Vegetation Treatments Using Herbicides on BLM Lands in 17 Western States PEIS* (USDI-BLM, 2007). The Challis Field Office tiered to this document in preparing the 2009 Challis -Salmon Integrated Weed Control EA.

Invasive species have been documented at 86 sites within or immediately adjacent to the CHMA. The species which have been documented and their number of occurrences are: Spotted knapweed *(Centaurea stoebe)* - 56; Leafy spurge (*Euphorbia esula*) – 13; Whitetop/Hoary cress (*Cardaria draba*) – 12; Diffuse knapweed (*Centaurea diffusa*) – 3; Canada thistle (*Cirsium arvense*) - 3; Black henbane (*Hyoscyamus niger*) -3; Russian knapweed (*Acroptilon repens*) -1; and Rush skeletonweed (*Chondrilla juncea*) -1. The vast majority of these sites are less than half an acre in size. Half of the inventoried sites occur along Highways 93 and 75, which are boundaries of the CHMA. In 2011, a total of 10.5 acres of chemical treatment was applied to weed sites throughout the CHMA.

Cheatgrass inventories have not yet been completed in the CHMA, so the extent of cheatgrass infestation is difficult to quantify.

3.5.2 Environmental Effects—Invasive Species

Alternatives 1-4
Wild horse gather activities would disturb soils in localized areas, primarily associated with capture sites and sorting/holding facility. Follow-up inspections by the BLM of these sites and treatment of any noxious weeds would prevent noxious weeds from invading and dominating adjacent native plant communities. There have been 14 gathers conducted in the CHMA since 1979. All of these have involved the use of trucks, trailers, domestic horses, and capture sites. An increase of invasive species has not been documented at any of the known capture sites; in most cases these sites are difficult, if not impossible to identify due to the recovery of native vegetation.

The BLM anticipates that the removal of wild horses over time would decrease overall impacts of wild horse use and proliferation of invasive, non-native species. As wild horses and livestock are managed within allocated forage levels, grazing pressure is reduced on native vegetation. Those native vegetation communities are then more resilient and better able to compete with non-native species.

Alternative 5 – No Action (Deferred Gather)
No impacts from the gather would occur. However, wild horse populations would remain over appropriate management levels and the impacts to native vegetation from wild horse grazing or trampling would increase. Impacts to the present plant communities could lead to an expansion of noxious weeds and invasive non-native species.

3.6 Wetlands/Riparian Zones

3.6.1 Affected Environment

Riparian-wetland habitats (i.e., riparian ecosystems) are generally defined as a body of water with its adjacent soil and vegetation (Hall and Bryant 1995). Healthy riparian ecosystems possess the following indicators: 1) adequate riparian-wetland vegetative cover present to protect banks and dissipate energy during high flows; 2) streambank vegetation, often called the "greenline" is comprised of those plants or plant communities that have root masses capable to stabilize streambanks; and 3) age class and structural diversity of riparian/wetland vegetation. Riparian-wetland vegetation should also reduce erosion by stabilizing streambanks, providing shade, filtering sediment, aiding floodplain development, dissipating energy, delaying flood water, and increasing groundwater recharge.

The riparian land cover includes natural vegetation dominated or characterized by shrub and/or herbaceous species requiring environmental conditions of moderate moisture and temperature. In semi-arid environments, riparian-wetland areas make up a relatively small but productive and resilient portion of the landscape, exhibiting vegetative or physical attributes reflective of the influence of water. They are important for the ecosystem functions they serve, such as floodplain and ground-water storage, water transport, improved water quality, and fish/wildlife habitat. The majority of the drainage network located within the CHMA consists of dry channels receiving water only during periods of high snow melt and/or intense precipitation. Relatively few stream miles (5% within the CHMA) convey water perennially; the stream miles by stream type are given in Table 12.

Proper Functioning Condition (PFC) is a qualitative method for assessing the condition of riparian-wetland areas. The term PFC is used to describe both the assessment process, and a defined, on the-ground condition of a riparian-wetland area. There are PFC methods for both streams (lotic) and springs (lentic) (USDI-BLM, 1998, 2003). PFC was designed as a baseline for the purpose of inventorying riparian areas and wetlands managed by BLM. While PFC is meant to establish a baseline, it is not a quantitative monitoring approach and is not meant for monitoring trend. Multiple Indicator Monitoring (MIM) has been developed for the purpose of monitoring stream channels and stream side vegetation on those streams and small wadeable rivers designated for monitoring. This is done for the purpose of determining the condition and trend of streambanks, channels and streamside vegetation. MIM measures the effectiveness of management strategies over 5 to 10 year time scales establishing trend. The metrics include but are not limited to: greenline-to-greenline width, streambank alterations, greenline vegetation composition, stubble height, woody species age class, and utilization on woody species. These metrics are then implemented in determining the ecological status of the greenline vegetation, the site wetland rating, and the streambank stability (USDI-BLM 2011a). Greenline analysis was conducted prior to MIM for the purpose of monitoring the streambank vegetation and determined the seral status and site wetland rating for a given DMA [Designated Monitoring Areas] (Winward, 2000). While both methods are similar the key difference is that the Winward Greenline Method was based upon steps of community type whereas the MIM method uses a plot (50 cm x 20 cm) placed at 80 or more locations within the DMA. The MIM method is considered more precise and/or repeatable than the Winward Greenline method. Photo monitoring has also been commonly employed by the CFO at streams and springs for implementation monitoring and to qualitatively assess conditions and trend.

Stream flow regimes in CHMA are indicative of a snow melt dominated system with highest flows occurring in July (870 CFS [Cubic Feet per Second] mean monthly discharge on East Fork Salmon River at USGS Gauge) and lowest flows occurring in January and February (79 CFS mean monthly discharge on East Fork Salmon River at USGS Gauge). The USGS Gauge is located near the mouth of the East Fork of the Salmon River and recorded surface flow from September 1928 – September 1939 & May 1973 – September 1981. The maximum flow 4,020 CFS was recorded on June 17, 1974 and the minimum flow 26 CFS was recorded on November 21, 1977. High magnitude flow events are typically associated with intense precipitation and/or high snow melt. This area is subject to high intensity short duration thunderstorms which result in episodic intense stream flow. Base flow occurs in the winter as a result of the majority of the precipitation being stored as snow.

Table 12. Miles of Stream by Stream Type

Stream Name	Stream Miles	Stream Type
Unnamed Streams	550.5	Intermittent to Ephemeral
Bear Creek	1.6	Intermittent to Ephemeral

*Data obtained from PFC Database (USDI-BLM, 2011b)

The CHMA is divided between the East Fork Salmon River and the Warms Spring Creek watersheds. The underlying geologic units are predominantly limestone and dolostone formations (Fisher and Johnson, 1995) which favor infiltration over stream runoff, resulting in the presence of springs with consistent perennial flow where portions of this infiltrated water re-emerges on these allotments. Riparian habitats involve not only riverine ecosystems, but also include vegetation associated with seeps, springs brooks, lakes, and ponds. The greenline plant community structure within riparian areas may vary depending on frequency of flooding, amount of scouring, and past disturbance. The riparian areas in the CHMA commonly support woody plant species including black cottonwood, quaking aspen, douglas-fir, mountain maple, wood's rose, willow species, red-osier dogwood, chokecherry, gooseberry, currant; as well as mesic forbs, grasses and desirable hydric species like nebraska sedge, beaked sedge and baltic rush.

The Spar Canyon sub-watershed is the first major drainage on the east side of the East Fork Salmon River traveling upstream from its mouth. Spar Canyon has no perennial tributary streams. Spar Canyon itself is 10 miles of deeply incised (10-20 feet) ephemeral stream channel that only conveys water during spring runoff and during occasional summer thunderstorms, and does not support riparian vegetation corridors. Spar Canyon has a number of ephemeral tributaries and springs including Bear Wallow, Tub Spring, Gossi Spring, White Colt Spring, Grey Stud Spring, and Sorrel Spring (IDEQ, 2003).

The entirety of the Road Creek Watershed with the exception of a small portion of privately owned lands proximal to the East Fork Salmon River is located in the southwestern portion of the CHMA. Road Creek is a tributary of the East Fork of the Salmon River and is perennial downstream of a spring located in the NW¼SW¼ & SW¼NW¼ sec. 36, T. 10 N., R 20 E., B. M. Road Creek has three perennial tributaries; Mosquito Creek, Horse Basin Creek and Bear Creek as well as multiple unnamed ephemeral dry washes; Pine Creek is an intermittent to ephemeral spring dominated tributary to Corral Creek which is a tributary to Horse Basin Creek. Road Creek and its perennial tributaries were assessed using the PFC protocol and the functionality determinations are given in Table 13 (Map 1).

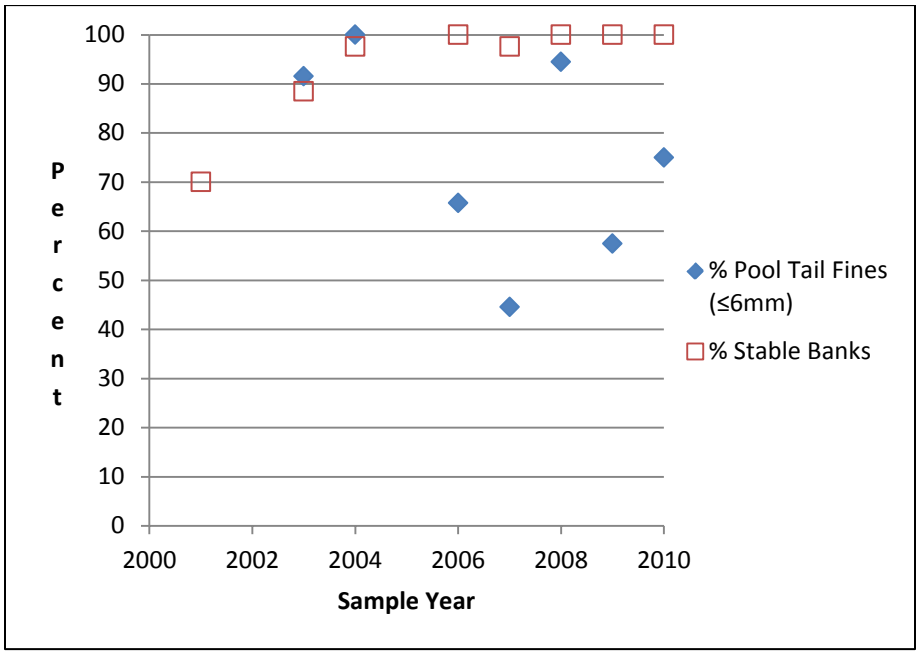
Riparian monitoring occurs on Road Creek at five key areas. The key area MIM and Greenline Analysis monitoring results are given in Table 14. While the PFC data from 1994 indicated Road Creek was functioning at risk to nonfunctioning throughout the entire reach, the MIM and Greenline Analysis data indicate that riparian areas within Road Creek are at or near potential community and therefore likely functioning appropriately at this time. Based on monitoring horse use has been apparent in the Horse Basin and Corral Basin Creek drainages as well as along Road Creek. Wild Horse use in Horse and Corral Basin drainages is widely distributed and often season long; whereas use along Road Creek is seasonally focused in winter and apparent at localized areas. Horse use has not been apparent along Bear and Mosquito Creeks above their confluences into Road Creek. In those portions of the CHMA where surface water predominately occurs as upland springs (outside of the Road Creek Watershed) wild horse use of riparian areas/wetlands is focused at upland springs.

There were two lentic PFC's conducted on two springs located at the head of Chicken Creek on September 28, 1999. The spring located furthest up the drainage was approximately 0.1 acres and was rated as functioning at risk with trend not apparent. The second spring was downstream, 1.5 acres in size and was rated in proper functioning condition. Wild horses do not typically use the Chicken Creek drainage and therefore they were not a factor contributing to functionality at these springs. The majority of the springs within the CHMA were surveyed (1993-1994) for the Snake River Basin Adjudication of water rights. This survey found there are 12 ponds, 252 seeps and 26 spring brooks (Map 2). This survey found that use by wild horses, cows or big game was common throughout the CHMA.

Table 14. Riparian MIM and Greenline Analysis Monitoring Summary (1999-2012)							
Stream	Year	Key Area	Monitoring Method	Greenline Ecological Status Rating	Site Wetland Rating	Streambank Stability (%)	% Fines
Road Creek	1999	1	Greenline Analysis	Late Seral	Good		
Road Creek	2010	1	MIM	Potential Natural Community	Good	94%	49%
Road Creek	2005	3	Greenline Analysis	Potential Natural Community	Good		
Road Creek	2006	4	Greenline Analysis	Potential Natural Community	Good		
Road Creek	2010	4	MIM	Potential Natural Community	Very Good	97%	56%
Road Creek	2012	5	MIM	Potential Natural Community	Good	99%	39%
Horse Basin Creek	2007	2	MIM	Late Seral	Good	56%	

Lone Pine Creek is located in the northeastern portion of the CHMA located on Bradbury Flat. The upper reaches of Lone Pine Creek are known to be perennial, but surface water is discontinuous and the channel becomes dry typically more than 1 mile before its confluence with Warm Springs Creek with xeric species growing within the conveyance. Riparian monitoring occurs at a single photo point on Lone Pine Creek. Approximately 0.8 mile of the creek is located within an exclosure and this reach was assessed using the PFC protocol in October 1998, and was determined to be functioning at risk with an upward trend. The exclosure was constructed in 1992 for the purpose of excluding the majority of the perennial reach from grazing. Lone Pine creek within the exclosure is characterized by a narrow incised channel and receives sediment from its ephemeral tributaries during high intensity precipitation events resulting in siltation and sedimentation along this reach. The stream is also limited in its floodplain extent to the width of the stream bottom within the incised reach. Other water sources in the vicinity of Bradbury Flat are associated with ephemeral water courses; and springs which create spring brooks which flow for short distances before sinking. Population inventories and field observations indicate wild horses routinely use this area year round.

Broken Wagon Creek is located in the southeastern portion of the CHMA. Water distribution proximal to Broken Wagon Creek consists of the creek drainage including tributaries as well as upland seeps and springs, most of which do not convey surface water to the creek. There are multiple unnamed upland springs forming the headwaters of Broken Wagon Creek. The creek



consists of approximately 1.3 miles of perennial reaches with the remainder classified as intermittent to ephemeral (see Table 12). Therefore it is likely that the reaches of the streams classified as non-functional during the 1994 PFC assessments were dry and may not have the potential to support a thriving riparian vegetation community. Population inventories and field observations indicate wild horses routinely use this area year round.

The 0.2 miles of the East Fork of the Salmon River is located along the southwestern margin of the CHMA at the mouth of Dry Hollow. This reach is in Proper Functioning Condition and is bounded to the west by steep topography which is prohibitive to horse access. Horse access is further limited by an east-west drift fence located at the northern margin of the mouth of Dry Hollow. Wild horses have not been observed in Dry Hollow during the last 7 population inventories (2000-2012).

The Pacific Anadromous Fish Strategy (PACFISH) and Inland Fish Strategy (INFISH) Biological Opinion Effectiveness Monitoring Program (PIBO – EM) for aquatic and riparian resources began development in 1998 following the ESA listing of steelhead and bull trout. A federal interagency effort to develop a large-scale monitoring program to determine whether PACFISH/INFISH management practices are maintaining, degrading, or improving biological and physical attributes, processes, and functions of riparian and aquatic habitats throughout the Upper Columbia River Basin. Interagency monitoring efforts at randomly selected streams in the upper Columbia River Basin began in 2001, typically on 5-year cycles. More information regarding the PIBO-EM program is available online (www) at http://www.fs.fed.us/biology/fishecology/emp/index.html. Relative to the CHMA, Road Creek has two monitoring locations associated with PIBO-EM. A DMA site, RC-KA-01, is used by the BLM for implementation monitoring (e.g. short term indicators of grazing use), and roving PIBO-EM crews conduct effectiveness monitoring (e.g. long term indicator of habitat condition or recovery). Approximately 0.1 miles upstream of RC-KA-01 there is an "Integrator" monitoring site. At this site PIBO-EM crews collect effectiveness monitoring data. This occurs typically at shorter intervals than 5 years (see Map 1).

At the Integrator reach on Road Creek effectiveness monitoring was conducted by PIBO monitoring crews 8 times from 2001 to 2010 (Figure 1). Between 2005 and 2010 pool tail fines appear cyclic; likely resultant of periodic transport limited deposition in this carex dominated reach, and periods of sufficient energy to transports fines. The high levels of bank stability are related to abundant root-binding greenline vegetation, resistant to hoof alteration. This data shows that this reach has attained/ maintained achievement of the riparian monitoring objective (>= 90% bank stability) pursuant to the Challis RMP (USDI-BLM, 1999) and that major decreases in fine sediment may not be possible due to geomorphology, beaver influence and perturbations resultant from yearlong wild horse and wildlife presence, seasonal grazing and the presence of the road along the creek.

Figure 1. Effectiveness monitoring data collected by PIBO crews 2001 to 2010 at Integrator Reach on Road Creek upstream of BLM DMA RC-KA-1.

3.6.2 Environmental Effects-- Wetlands/Riparian Zones

Alternative 1

Direct effects of horse gathering on riparian areas would vary based upon the distribution of the horses across the CHMA. Gather personnel would select capture sites based upon wild horse's distribution at the time of the gather. If the horses are distributed within the vicinities of riparian areas/wetlands a potential exists that horses may need to be gathered proximal to riparian areas. The gathering of horses near riparian areas has the potential to result in localized effects as a result of riparian areas/wetlands being traversed by the horses. For example during the 2009 gather 4 horses crossed Road Creek once each during the gather. These effects could consist of bank alterations from horses stepping on the stream banks. Moreover, the effects of horses crossing riparian areas/wetlands during a gather are not anticipated to be discernible from the number of crossings horses would make if a gather were not occurring because the horses cross the streams in the CHMA regularly.

There are three existing potential wild horse capture sites adjacent to Road Creek within the RHCA (Riparian Habitat Conservation Area), identified in the Challis RMP (P. 83-84, Attachment 4). These are categorized in the Challis RMP as: 1) a 300-foot buffer along perennial, fish bearing streams; 2) a 150-foot buffer along perennial non-fish bearing streams; 3) a 150-foot buffer around ponds, wetlands, lakes, reservoirs and wetlands greater than 1-acre in size; 4) and a 100-foot buffer around wetlands less than 1-acre and landslides / landslide prone areas (USDI-BLM, 1999a; USDI-USDA 1995b,c) the potential capture sites are proposed for use during the 2012 gather, and have been used in previous gathers. One site is located just downstream of the confluence of Horse Basin Creek and another located on the road approximately 1/3 mile downstream of the Bear Creek confluence. The most upstream proposed

capture site is near the North Fork Sage Road, between RC-KA-03 and RC-KA-04 (see Map 1). However, it is likely that only one site in the Road Creek watershed would be used during proposed wild horse gather operations. For example, during the 2004 and 2009 gathers only one capture site along Road Creek was used. The capture sites are located on the upstream side of the road among xeric flora. The effects of holding wild horses within these capture sites for a short duration (most would be only for hours, some could be held overnight) would be trampling of vegetation as well as loosening of surface soil, which could result in increased runoff from this site during subsequent precipitation events. Any excess sediment would be primarily buffered by the existing road. Furthermore, because the gather is likely to occur in the fall any subsequent precipitation would likely occur as snow not resulting in immediate runoff. The area would likely re-vegetate during the following spring growing season. Therefore, the gather is not likely to result in increased percent fines in perennial streams. In addition the immediate downstream reaches are influenced by beaver activity that has created multiple ponds acting as natural sediment traps. Any new capture sites would be outside of the RHCA to eliminate effects to streambanks and riparian vegetation.

Under this alternative wild horse population levels would undergo a short term (3-5 years) population reduction; this would likely result in an in kind short term reduction in the effects of horses to riparian areas and wetlands allowing for streams within the CHMA to continue to maintain or progress towards potential natural community. The AML was established by the RMP and where greenline monitoring and MIM have occurred these sites have continued to rate as late seral or potential natural community (see Table 14). The high bank stability indicates that the maintenance of AML in the CHMA has resulted in maintenance or recovery of riparian areas. Where wild horses effect upland springs (e.g. trampling, foraging, defecation) a short term reduction in the intensity and frequency of wild horse use would occur. There is a non-uniform spatial distribution of wild horse use on the upland springs within the CHMA. Those springs that receive relatively focused wild horse use are anticipated to continue to receive relatively focused wild horse use.

Alternative 2

The environmental effects to riparian and wetlands as a result of a gather result from population size and the extent of gather operations (e.g. number of trucks on roads, number of captures sites etc.). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 3, and 4 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to riparian and wetland resources would be the same under this alternative as alternative 1.

Alternative 3

The environmental effects to riparian and wetlands as a result of a gather result from population size and the extent of gather operations (e.g. number of trucks on roads, number of captures sites etc.). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 2, and 4 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to riparian and wetland resources would be the same under this alternative as alternative 1.

Alternative 4
The environmental effects to riparian and wetlands as a result of a gather result from population size and the extent of gather operations (e.g. number of trucks on roads, number of captures sites etc.). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 2, and 3 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to riparian and wetland resources would be the same under this alternative as alternative 1.

Alternative 5
Under this alternative no direct effects related to horse gather activities would. Rather than a short term reduction of horse population (as described under alternatives 1-4), the horse population would continue increasing. An increase of use by wild horses at riparian areas and upland springs is anticipated. For example monitoring data indicates that when the Appropriate Management Level of 185 is exceeded, wild horse effects (trampling, vegetation utilization, defection etc.) can intensify at riparian areas and upland springs. Livestock use criteria are used to manage the intensity of livestock grazing. Stubble height and bank alteration criteria have been set for the perennial streams in the CHMA by the Challis RMP. Use of riparian areas by wild horses has resulted in exceedance of these livestock grazing standards. For example, in 2003 there were 203 horses counted during the census conducted that year and livestock grazed from June 16 to July 11. When livestock were done grazing at Horse Basin Creek Key Area 2 the stubble height was 4 inches, on October 23 the stubble height was at 2 inches (the standard is 3 inches pursuant to the Challis RMP) and the bank shears were 26% (the Standard is less than 10% pursuant to the Challis RMP [USDI-BLM, 1999a]). In 2006 Horse Basin was rested from cattle grazing and 231 horses were counted during the census that year, stubble height was measured at Horse Basin Creek Key Area 2 at 2 inches. In both of these cases the exceedance of the grazing use criteria was attributable to horse use (see Appendix K).

Therefore as a result of this alternative it is likely that the springs and stream riparian areas in the CHMA would receive increased intensity and frequency of wild horse use. This has a potential to result in altered vegetation communities typically resulting in a lower seral stage. Lower seral stages have less recruitment of woody species reducing shade and stability of the site because binding roots associated with hydric herbaceous and mature trees/shrubs are not as prevalent. This results in an overall reduction in the spatial extent of the riparian area whether it is a stream or a spring site (USDI- BLM, 1998, 2003). This would result in riparian areas within the CHMA being more vulnerable to future disturbance such as drought, high flow events etc. and becoming nonfunctional.

3.7 Water Quality

3.7.1 Affected Environment

Approximately 346 stream miles were assessed within the CHMA by the IDEQ (Idaho Department of Environmental Quality) pursuant to section 305(b) of the CWA (Clean Water Act 33 U.S.C. §1251 et seq. 1972). Streams which are assessed pursuant to this section but do not meet the IDWQS (Idaho Water Quality Standards) are 303(d) listed, meaning that water body is classified as water quality impaired. Standard 7 of the Idaho Rangeland Health Standards states that surface and ground waters on public land shall comply with the IDWQS. The 305(b) water bodies assessed included perennial, intermittent and ephemeral stream reaches (see Table 12). Of these, approximately 95 stream miles were listed as impaired because they did not meet one or more of the IDWQS.

The majority of the stream miles within the CHMA are ephemeral to intermittent (see Table 12) under Riparian Areas and Wetlands) and only flow during periods of intense precipitation and/or high snow melt. Of particular importance to the streams located on the CHMA is the relationship between IDWQS and intermittent waters. An intermittent stream is defined (in Idaho Administrative Code 58.01.02.003.51) as a stream that has a period of zero flow for at least one week in most years. Where flow records are available a stream with a seven day average flow of less than 0.1 CFS is considered intermittent. Section 070.07 of IDWQS (Idaho Administrative Code 58.01.02.070.07) addresses the application of the IDWQS to these types of streams. IDWQS apply to intermittent streams during periods of optimum flow sufficient to support the beneficial uses for which the intermittent stream has been designated. In many cases, intermittent streams have not been designated and are protected for the default uses of cold water biota and secondary contact recreation (recreation that does not result in prolonged and intimate contact with the water when small amounts of water are likely to be ingested). Optimum flow is described as at least 1 CFS for aquatic life (cold water aquatic life) and at least 5 CFS for recreation uses. When flows drop below these threshold values, the IDWQS no longer apply to the given water body (IDEQ, 2001). The statuses of streams which are located upon the CHMA are given in Table 15.

Table 15. 305(b) Streams located in CHMA		
STREAM	Status	length (miles)
Unnamed Streams		207.50
Unnamed Streams	303D LISTED	76.99
Bear Creek		5.35
Broken Wagon Creek	303D LISTED	7.76
Corral Basin Creek		7.78
East Fork Salmon River		0.20
Horse Basin Creek		6.87
Lone Pine Creek		8.50
Mosquito Creek		1.61
Mosquito Creek	303D LISTED	6.05
Road Creek		12.23
Road Creek	303D LISTED	2.90
Sheep Creek	303D LISTED	0.32
Warm Spring Creek	303D LISTED	1.00

Due to the large scope of assessing all of the water bodies in Idaho the IDEQ has divided these bodies into lumped assessment units. Many of these assessment units have multiple monitoring sites for conducting assessments, if any of the assessment sites do not meet the criteria for being fully functioning the entire assessment unit is typically considered impaired and consequently 303(d) listed. The majority of unnamed stream miles which were 303(d) listed were lumped into the Warm Springs Creek source to Hole in the Rock Creek unit; the reason this assessment unit is 303(d) listed is for not supporting cold water aquatic life with low flow alterations and sedimentation /siltation listed as the pollutants. This assessment unit includes areas east of Highway 93 outside of the CHMA. The majority of monitoring sites used by IDEQ were assessed when no water was present in the channel, and the sites were selected in reaches which are classified as intermittent to ephemeral see Appendix H. Warm Springs Creek below Hole in the Rock Creek is not 303(d) listed. Population inventories and field observation indicate that wild horses are present in this portion of the CHMA but they do not affect the perennial and or ephemeral nature of the streams at the locations where assessments were conducted.

There is a short reach of Broken Wagon Creek (1.3 miles) which is perennial in the CHMA. Broken Wagon Creek is listed from source to mouth for not supporting cold water aquatic life with low flow alteration and sedimentation/siltation listed as pollutants. The site monitored by

IDEQ is not within the perennial reach and was monitored at a time when the stream was dry (see Appendix H for IDEQ monitoring data). The portion of Sheep Creek between Highway 93 and the confluence with Warm Springs Creek as well as the entirety of the ephemeral to intermittent unnamed streams above the confluence of Broken Wagon Creek and Warm Springs Creek were lumped into the Broken Wagon Creek source to Mouth Assessment Unit. Population inventories and field observation indicate that wild horses are present in this portion of the CHMA but they do not affect the perennial and or ephemeral nature of the streams at the locations where assessments were conducted.

The majority of perennial miles within the CHMA occur in the Road Creek watershed. Mosquito Creek is a tributary to Road Creek and is 303(d) listed from source to mouth for not supporting cold water aquatic life and salmonid spawning with combined biota/habitat bio-assessments (aquatic habitat conditions) listed as the pollutant. This determination was based upon a single 1998 sample taken 30 meters above the confluence into Road Creek and is not representative of typical habitat conditions within Mosquito Creek; during this sample IDEQ did not document salmonids, however westslope cutthroat have been documented by BLM electrofishing efforts in this reach. Furthermore IDEQ attempted to monitor a location in upper Mosquito Creek in 2004 and found the site to be inaccessible due to dense woody vegetation. Road Creek is 303(d) listed from confluence of Bear Creek downstream to the confluence of Horse Basin Creek for not supporting salmonid spawning with biota/habitat bioassessments (aquatic habitat conditions). Population inventories and field observation indicate that wild horses are present in this portion of the CHMA and the relative influence of wild horses on water quality determinations is unknown and the effects to aquatic habitat conditions as a result of the presence of wild horses is disclosed under fisheries.

3.7.2 Environmental Effects

Alternative 1

There is one capture site located along the 303(d) listed reach of Road Creek between the confluences of Mosquito Creek and Bear Creek. Any new capture sites would occur outside of the RHCA. Sedimentation and Siltation is the pollutant which is most likely to result from use of the capture sites, however a substantial contribution to streams within the CHMA is not anticipated as a result of the of capture sites. A low potential exists for wild horses to step in streams while being gathered (see riparian area and wetlands for further discussion). This could result in bank shearing and/or stepping in fine substrate sediments creating short duration localized turbidity. Turbidity is the measure of the cloudiness or haziness of a water body and is used as a method to determine sediment loading. The IDWQS for meeting cold water aquatic life beneficial use is: *Turbidity, below any applicable mixing zone set by the Department, shall not exceed background turbidity by more than fifty (50) Nephelometric Turbidity Units (NTUs) instantaneously or more than twenty-five (25) NTU for more than ten (10) consecutive days* (IDAPA 58.01.02). IDWQS would not be violated as a result of gathering horses because of the short duration of the gather (typically less than 3 days at any capture site) and the low potential for horses to cross streams as a result of this action. Effects to salmonid spawning and TES Fish (cold water aquatic life) are disclosed under Fisheries.

As a result of this gather, a short term decrease in horse population would occur. As discussed under section 3.6 there are effects to riparian areas which in turn affect water quality. These effects are a reduction in; 1) foraging which allows for canopy (shade) maintenance/recovery which influences water temperature, 2) defecation which leads to fecal coliform presence in surface waters and 3) bank destabilization which can result in sedimentation/siltation. The intensity and frequency of use of wild horses at streams and springs would receive a short term in kind reduction. However those water bodies associated with riparian areas which receive relatively focused wild horse use would continue to do so.

Alternative 2
The environmental effects to water quality as a result of a gather result from population size and the extent of gather operations (e.g. number of trucks on roads, number of captures sites etc.). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 3, and 4 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to riparian and wetland resources would be the same under this alternative as alternative 1.

Alternative 3
The environmental effects to water quality as a result of a gather result from population size and the extent of gather operations (e.g. number of trucks on roads, number of captures sites etc.). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 2, and 4 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to riparian and wetland resources would be the same under this alternative as alternative 1.

Alternative 4
The environmental effects to water quality as a result of a gather result from population size and the extent of gather operations (e.g. number of trucks on roads, number of captures sites etc.). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 2, and 3 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to riparian and wetland resources would be the same under this alternative as alternative 1.

Alternative 5
Under Alternative 5, it is likely that the springs and stream riparian areas in the CHMA would receive increased intensity and frequency of wild horse use. This has a potential to result in altered vegetation communities typically resulting in a lower seral stage. Lower seral stages have less recruitment of woody species reducing shade and stability of the site because binding roots associated with hydric herbaceous and mature trees/shrubs are not as prevalent. This results in an overall reduction in the spatial extent of the riparian area whether it is a stream or a spring site (USDI- BLM, 1998, 2003). A decrease in canopy/shade would result in an increase in water temperatures. A decrease in bank stability would result in increased sedimentation. The increase in numbers of wild horses would increase the fecal loading of springs and streams. Therefore the

cessation of gathering wild horses for period of up to 10 years would affect water quality such that more water bodies would likely not meet the IDWQS and thereby increase the miles of 303(d) listed streams on the CHMA.

3.8 Threatened, Endangered, and Sensitive Fish; Fisheries

3.8.1 Affected Environment

Species and Critical Habitat

This section focuses on the distribution of threatened / endangered fish species, BLM sensitive and Idaho State fish species of concern, and water bodies designated as critical habitat that border or lie within the CHMA. The United States Fish and Wildlife Service (USFWS) and the National Marine Fisheries Service (NMFS) have, under ESA, identified the following threatened and endangered fish species and habitat that occur in the area administered by the CFO:

- **Snake River sockeye salmon** (*Oncorhynchus nerka*) (Endangered) (Federal Register 56FR58619). Critical habitat has been designated for Snake River sockeye salmon (Federal Register 58FR68543). However, the designation is limited to the Salmon River.

- **Snake River spring/summer Chinook salmon** (*Oncorhynchus tshawytscha*) (Threatened) (Federal Register 57FR14653). Critical habitat has been designated for Snake River spring/summer Chinook salmon and includes "river reaches presently or historically accessible…to Snake River spring/summer Chinook salmon" (Federal Register 58FR68543).

- **Snake River steelhead** (*Oncorhynchus mykiss*) (Threatened) (Federal Register 62FR43937). Critical habitat has been designated for Snake River Basin steelhead (Federal Register 70FR52630) and includes numerous streams in the Upper Salmon River watershed and the BLM Challis Resource Area.

- **Columbia River bull trout** (*Salvelinus confluentus*) (Threatened) (Federal Register 63FR31647). Critical habitat was designated for bull trout on September 26, 2005, and initially did not include the Salmon River. On October 18, 2010, a revised final designation of critical habitat was published which included mainstem rivers and numerous tributaries the Upper Salmon River watershed and BLM Challis Resource Area (Federal Register 75FR63898).

Although not ESA listed as threatened or endangered, westslope cutthroat trout (*Oncorhynchus clarki lewisi)* is an Idaho State species of concern and a BLM sensitive species. Westslope cutthroat trout occur in portions of the CHMA (USDI-BLM 1999a), and that benefit peripherally from stipulations and conservation measures intended to prevent effects to listed salmonids and designated critical habitat. Therefore, westslope cutthroat trout are discussed concurrently. Although designated critical habitat abounds in in the Salmon River, East Fork Salmon River and many tributaries, relatively few historically accessible streams and little designated critical

habitat occurs in the CHMA. Designated critical habitat for ESA listed salmonids (Map 3) and documented presence within and adjacent to the CHMA is summarized below in Table 16.

Table 16. Documented T/E and Sensitive Fish Species Presence and ESA Designated Critical Habitat Distribution Within the CHMA.

Stream Name	Stream Miles[1]	Stream Type[1]	T/E and Sensitive Fish Presence[2]	ESA Designated Critical Habitat
Unnamed Stream	550.5	Intermittent to Ephemeral	None	None
Bear Creek	1.6	Intermittent to Ephemeral	None[3]	CHS
Broken Wagon Creek	6.4	Intermittent to Ephemeral	None	None
Corral Basin Creek	0.9	Intermittent to Ephemeral	None	CHS

[1]Data compiled and distances estimated with a GIS using the USGS National Hydrology Dataset. [2]Based on known documented observations collected by BLM-CFO between 1994 and 2012, IDEQ, or IDFG (IDEQ, 2010); [3]The intermittent / ephemeral reach of Bear Creek occurs in a headwaters mesic meadow with insufficient surface water / stream channel habitat to support salmonids.

BLT = bull trout, CHS = Chinook salmon, STH = anadromous steelhead, RBT = resident / fluvial rainbow trout, WSCT = westslope cutthroat trout, None = no T/E or sensitive species present, UNK = fish presence unknown but potentially accessible by fish in downstream occupied habitat

Land ownership within the CHMA encompasses approximately 154,176 acres of BLM, 9,472 acres State of Idaho, 1,088 acres of private lands, with approximately 55 miles of perennial stream within the CHMA. The entire CHMA occurs in the Upper Salmon River Basin – 4th Field Hydrologic Unit Code (HUC) or USGS Cataloging Unit 17060201 (ISU 2012). The Upper Salmon River Basin (1.5 million acres) includes the mainstem Salmon River and numerous fish bearing tributaries (including the East Fork Salmon River) from the headwaters near Stanley, ID extending downstream to the mouth of the Pahsimeroi River near Ellis, Idaho. The CHMA is also included in the Upper Salmon River Major Population Group, used by NMFS to track the status and recovery of ESA listed anadromous (e.g. ocean going) salmonids (NMFS 2011; Ford

2010). However, relatively little fish habitat occurs in the CHMA because of distinctly volcanic geology and a preponderance of naturally intermittent or ephemerally wetted stream channels that historically and currently preclude occupancy by fish in most drainages which have only infrequent surface water conveyance to mainstem streams and rivers. Native fish and/or introduced salmonids are only known to occur in ≈5.1% of the total stream / conveyance miles within the CHMA, almost entirely located within Road Creek drainage (Table 16; Map 3).

The northwestern margins of the CHMA are bordered by State Highway 75 and the mainstem Salmon River and the southwest margins are bordered by the East Fork Salmon River and the East Fork Road. The southern boundary of the CHMA extends to the ridgeline drainage divide between Herd Creek and Road Creek in the Upper Salmon River watershed and the divide between Road Creek and Sage Creek in the Big Lost River Basin (4th Field HUC or USGS Cataloging Unit 17040218). The eastern margins of the CHMA are bordered by State Highway 93 and Warm Springs Creek, predominately occurring on private lands. The northern apex of the Challis CHMA is bounded by private lands developed for agriculture and home sites and State Highway 93 (Map 3).

The Salmon River, East Fork Salmon River, and Herd Creek all bound portions of the CHMA and are occupied designated critical habitat for ESA listed fish species including, Chinook salmon, steelhead, and bull trout. Spawning and rearing by anadromous Snake River Chinook salmon and Snake River steelhead has been assessed by Idaho Department of Fish and Game via aerial Chinook Salmon spawning redd counts, hatchery weir operations, and stream sampling and spawning surveys conducted by several state, federal, and tribal fisheries personnel. Resident Columbia Basin bull trout, westslope cutthroat, and rainbow trout *(Oncorhynchus mykiss)* are widely distributed throughout the Upper Salmon River Basin and occur in reaches of the Salmon River, East Fork Salmon River, and Herd Creek drainage which border the CHMA (NMFS 2011; USFWS 2010; USFWS 2002; USDI-BLM 1999a, 1999b, 1999c, 1999d, 1999e). The presence of Sockeye Salmon relative to the CHMA is limited to upstream migration by adults and downstream migration by juveniles in the adjacent reaches of the mainstem Salmon River en-route to Redfish Lake and the Sawtooth Fish Hatchery near Stanley ID, and the Pacific Ocean, respectively (IDFG 2011).

Within the boundaries of the CHMA a limited reach (≈0.2 miles long) of the East Fork Salmon River exists (Table 16) but is bounded by steep bedrock topography and results in infrequent wild horse presence proximal to this reach. Relative to the CHMA the remainder of designated critical habitat and stream reaches occupied by native fish and/or introduced salmonids is limited to the Road Creek drainage (USDI-BLM 1999a, 1999b, 1999c, 1999d, 1999e). Road Creek and its tributaries, while not designated by USFWS as critical habitat for bull trout or by NMFS for Snake River Steelhead, were included in the broader designation of critical habitat for Chinook salmon and essential fish habitat under the Magnuson-Stevenson Act. Other drainages within the CHMA such as Malm Gulch, Spar Canyon, and the Warm Springs Creek watershed with tributaries Lone Pine Creek and Broken Wagon Creek have limited perennial reaches and were unlikely to be historically accessible by Chinook salmon or other native fish (Table 16). This is because surface flows infiltrate into alluvium and often do not convey surface water adequate to maintain riparian corridors or stream channels capable of supporting fish. As ephemeral drainages approach their receiving waterways, their surface water conveyances are often absent

or become diffuse which further limits ephemeral surface water connectivity to only during extreme episodic precipitation events. In the case of Warm Springs Creek, historical disconnection from the Salmon River and geothermal influences has prevented the establishment of a native resident fish population in the Warm Springs Creek watershed (NMFS 2011; IDEQ 2003). Thus, with the exception of Road Creek, drainages in the CHMA were unlikely to be historically accessible by fish in the mainstem and East Fork Salmon Rivers, are not occupied by fish, and thus are not considered critical habitat.

Road Creek and its tributaries drain towards the East Fork of the Salmon River and constitute vast majority (≈79.2%) of perennial reaches on named streams in the CHMA (Table 16). Perennial Road Creek tributaries known to be occupied by native salmonids include: Mosquito Creek, Bear Creek, and Horse Basin Creek (Table 16). Snake River spring/summer Chinook salmon and steelhead are unlikely to currently occupy potentially historic spawning and rearing habitats in Road Creek due to a combination of the county road culvert, stream diversions, and flow-losing intermittent reaches in the lower ≈3 miles of Road Creek (USDI-BLM 2004; USDI-BLM 1999b). Beaver activity influences most BLM administered reaches of Road Creek from approximately Mosquito Creek to Chicken Creek and among private lands in lower Road Creek which can influence fish distribution and create a dynamic influence on habitat (Meehan 1991; Swanston 1991). For example, beaver ponds provide excellent rearing habitat juvenile salmonids, and increased aquatic productivity and low-velocity overwintering habitats are benefits. However, beaver ponds can displace spawning gravels via sediment deposition inherent to low-gradient stream impoundments and elevated stream temperatures detrimental to salmonids can also result.

The ability of salmonids to freely move within a watershed is essential to reproduction, foraging, and seeking thermal refugia during temperature limiting times of the year (July – August). Westslope cutthroat trout are the most widely distributed salmonid within Road Creek and its perennial tributaries. This distribution is supported by perennial surface water connectivity among its major tributaries, which allows fish to seek thermal refugia or spawning habitats. In Road Creek, naturally occurring intermittent reaches can necessitate such fish movement, and human barriers can further fragment habitats and impede fish migration (Meehan 1991). A culvert fish passage inventory was conducted for the Challis Field Office in 2004. Three Road Creek culverts were assessed as barriers to fish movement based on excessive slope and perched outlets, which one located near the East Fork Salmon River confluence on the East Fork Road (downstream of the CHMA boundary), and two in upper Road Creek on BLM lands (USDI-BLM, 2004). Road culverts which impeded fish passage have been reduced in Road Creek since 2006; 2 culverts in upper Road Creek between RC-KA-03 and RC-KA-04 (Map 3) were replaced, and in 2008 westslope cutthroat trout were observed at RC-KA-04 during macroinvertebrate sampling near the upstream terminus of perennial reaches of Road Creek in spring-dominated habitat. The culvert over Horse Basin Creek, just above its confluence into Road Creek, was assessed as a possible impediment to fish passage and also replaced in 2006. However, intermittent surface waters and anthropogenic barriers (e.g. culvert at East Fork Road below CHMA boundary) in the lower reaches of Road Creek which fragment fish distribution would likely persist into the foreseeable future.

The Road Creek watershed within the CHMA, including mainstem Road Creek on BLM lands, and Mosquito, Bear, and Horse Basin creeks have documented to be occupied by resident westslope cutthroat trout, rainbow trout, possible hybrids and mottled sculpin, but steelhead, Chinook salmon and bull trout were documented as being absent, and attributed to anthropogenic impediments to fish passage (IDEQ, 2010; USDI-BLM 1999b, 1999d). This is based on past BLM electrofishing surveys in the 1990's and more recent visual observations. Limited sampling was conducted by IDEQ, and documented unknown salmonids in upper Road Creek, westslope cutthroat trout in Horse Basin and Bear Creeks, and several rainbow trout in lower Horse Basin Creek in 1997 and a possible 50-mm rainbow trout / unknown salmonid in Road Creek near RC-KA-01 on 8/1/2006.

Current fish presence, based on BLM electrofishing surveys conducted 6/7/2012 to 6/20/2012 throughout the Road Creek watershed from mouth to headwater terminus, included the same suite of species within the CHMA. It also appears fish from the East Fork Salmon River are unlikely to access and occupy habitat in Road Creek within the CHMA. A combination of westslope cutthroat trout, rainbow trout, salmonids visibly indicative of cutthroat x rainbow hybrids (Behnke 1992), and mottled sculpin were present at all sites sampled in the CHMA, except the most downstream parcel of BLM lands. Given intermittent reaches in upper (below DMA RC-KA-04) and the lower reaches of Road Creek, numerous beaver impoundments, volcanic geology and with substrate composition dominated by relatively fine particles, the presence of spawning gravel habitat is likely limited in distribution. This may suggest limited reproductive isolation, further complicated by anthropogenic fragmentation, and the presence of resident rainbow trout. While fish stocking was historically common place in the Upper Salmon River Basin, the contribution of this potential anthropogenic influence on fish presence or hybridization, also known to occur naturally, is unknown (Kozfkay 2012). Furthermore, spawning habitat for steelhead and access are likely precluded by substrate composition dominated by fine sediments inhibitive to steelhead spawning and passage impediments, respectively.

The June 2012 BLM electrofishing effort also included the lower reaches of Road Creek downstream of the East Fork County Road, and outside of the CHMA boundary. Here the confluence into the East Fork Salmon River occurs and there are perennial flows, apparently influenced by flow-gaining / recharge upstream on private lands. There was also a distinctly different fish assemblage, consisting of rearing anadromous salmonids and fish from the East Fork Salmon River, than potentially isolated resident populations upstream on BLM lands within the CHMA. The distribution of fish from the East Fork Salmon River into Road Creek may not extend beyond the lower ≈0.25 to 1.0 miles on private lands near the confluence with where access/egress to the river can occur. Two reaches (18 and 75m in length) below the East Fork Road on private lands near the mouth were electrofished by the BLM on 6/20/2012; relative to all reaches sampled in the Road Creek watershed, here the largest relative abundance of individuals occurred with a total of 29 rainbow trout and / or rearing steelhead (≈60 to 250mm TL) and 82 rearing Chinook salmon (≈30 - 90mm TL), a single bull trout (≈180mm TL), and mottled sculpin. However, upstream of this important spring influenced flow-gaining reach; there is a distinctly flow-losing reach, likely exacerbated by diversions and historic channel incision, where dry channel in the summer/fall or flows low enough to limit migration and occupancy occur. For example, of the 13 electrofishing reaches (stream length ranged 18 –

200m of sampled habitat) the most downstream portion of BLM lands on Road Creek, concurrent with the aforementioned intermittent reach, was the only reach sampled (stream length 200m) to not contain any fish.

Water Temperature

Removal of canopy cover over small streams can result in detrimental increases in water temperature (Powell et al. 2000). In a comparison of ungrazed exclosures to areas subject to season-long grazing in the Blue Mountain region of Oregon, Claire and Storch (1983) noted that the grazed section was devoid of shrub cover and daily water temperatures were 12°F higher than water temperatures inside exclosures. Elevated stream temperatures can be influenced by impacts such as increased stream widths, decreases in stream depth, reductions in overhanging bank cover and vegetation, or reductions in stream flow. Intermittent reaches which lose flow to infiltration can experience naturally elevated water temperatures, and beaver impoundments also can result in elevated stream temperature (Swanston 1991). The seasonal occurrence of livestock grazing and the persistent use by wild horses has resulted in localized accessible areas with destabilized streambanks and reduced vegetative cover, but predominately riparian vegetation is functioning appropriately and providing stream shading throughout most of Road Creek and its perennial tributaries. Further descriptions of riparian vegetation and bank stability are discussed under Wetlands / Riparian Zones (Table 14).

Relative to the CHMA, flow diversion and intermittent reaches likely influence stream flow and water temperature in the lower reaches of Road Creek. Further upstream where BLM administered lands contain most of the Road Creek drainage, recreational use and congregation of livestock and wild horses has resulted in localized areas of decreased bank stability and/or riparian vegetation density (Table 14). However, stream reaches have predominately dense intact riparian corridors resistant to streambank impacts from wild horses or livestock. Natural influences on water temperature in Road Creek occur as beaver impoundments which decrease velocity, accumulate fine sediments and increase water temperature, potentially to detrimental levels during temperature limiting times of the year (July-August). In combination with climactic variability, other natural influences on water temperature are likely spring dominated flow-gaining reaches where temperature maxima can be mediated by groundwater contribution; other apparent flow-losing reaches occur as well, which can exacerbate temperature maxima (Kondolf 1989).

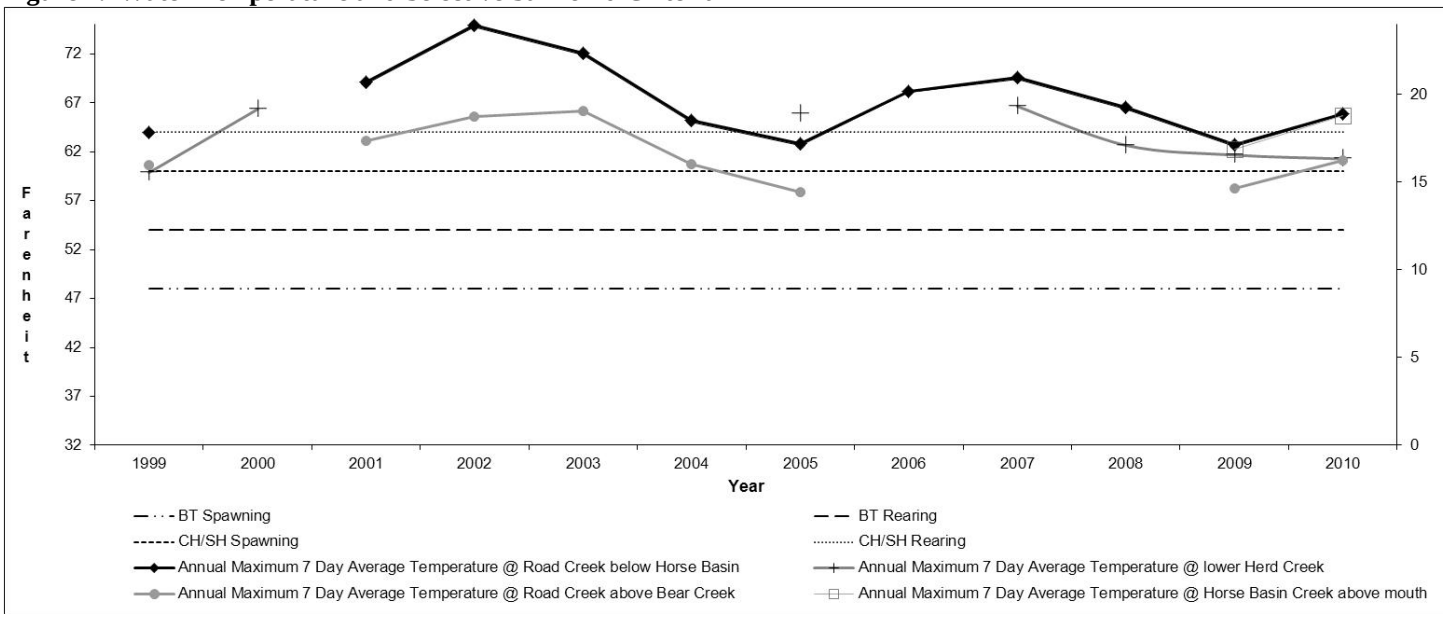

Table 17. PACFISH and INFISH Instream Temperature [1] Thresholds for ESA Listed Salmonids

Species	Spawning Season	Spawning Temperature (°C/ °F)	Rearing Temperature (°C/ °F)	Migration/Holding Temperature (°C/ °F)
Chinook Salmon	Summer	≤ 15.6/60	≤ 17.8/64	≤ 17.8/64
Steelhead Trout	Spring	≤ 15.6/60	≤ 17.8/64	≤ 17.8/64
Bull Trout	Fall	≤ 8.8/48	≤12.0/54	≤ 15.0/59

[1] *Measured as the 7 day maximum average instream temperature.*

Table 17 identifies PACFISH and INFISH instream temperature thresholds (USDI-BLM, 1995b, 1995c; USDI-BLM, 1999 b) important to listed salmonid behaviors and figure 2 displays annual temperature maxima displayed as the 7-day maximum average temperature in Road Creek and Horse Basin Creek. Water temperature is also presented neighboring Herd Creek, which contains spawning and rearing Chinook salmon and steelhead, and also contains reproductive populations of resident salmonids. Temperature thresholds for steelhead are presented below, and because they are similar to temperature thresholds for westslope cutthroat trout they are adequate for comparison. Based on annual temperature maxima presented in Figure 2, and a review of the seasonal progression of daily-water temperatures at Road Creek below Horse Basin, water temperatures likely exceed Chinook salmon and steelhead rearing thresholds for a portion of July and August, during most years; during 2009 the temperature maxima did not exceed this threshold (Figure 2). However, thermal refugia in the form of ground water gaining reaches and upper portions of Bear and Mosquito creeks likely exist, and seasonal water temperature maxima in Road Creek are unlikely to preclude occupancy by listed salmonids. For example, similar temperature maxima occur in neighboring Herd Creek which supports spawning and rearing by ESA listed salmonids (Chinook salmon, steelhead, and bull trout). Relative to westslope cutthroat trout, figure 2 suggests temperatures in lower Road Creek within the CHMA boundary exceed optimal growth conditions (>17°C) more often than Road Creek above its perennial tributaries, and has experienced temperature maxima (three seasons where data was available) greater that 20°C which can reduce survival of juvenile westslope cutthroat trout (Bear et al. 2007). However, downstream of the CHMA boundary flow-gaining reaches on private lands mediate what would otherwise be relatively high temperatures at the mouth, or even dry-channel.

Figure 2. Water Temperature and Selective Salmonid Criteria

Temperature data presented as the highest 7 day average maximum temperature recorded annually 1999 to 2010. BT Spawning = bull trout spawning temperature threshold, BT Rearing = bull trout juvenile rearing temperature threshold, CH/SH Spawning = Chinook salmon and steelhead trout spawning temperature threshold, CH/SH Rearing = Chinook salmon and steelhead trout juvenile rearing temperature threshold.

3.8.2 Environmental Effects

Alternative 1

The potential for proposed horse gather operations to have effects on fish or habitat is inherently low based upon the location of streams relative to the distribution of gather activities, and the limited extent of occupied fish habitat in the CHMA. In addition, elements of the proposed gather alternatives described below are expected to prevent any effects to ESA listed fish or habitat within and adjacent to the CHMA. The majority existing proposed capture sites used in previous wild horse gathers and sorting/holding facilities (Map 3) would occur ≥3-miles from habitat occupied by listed fish in Herd Creek, the mouth of Road Creek, the East Fork Salmon River or the Salmon River. These areas lie outside the potential gather area and horses occur there infrequently. During gather operations any wild horses proximal to these areas would be directed toward the CHMA interior, away from these substantial rivers or occupied habitat often bounded by State Highways, County roads, fenced private lands, and / or steep topography. Areas outside of the CHMA where horses are expected to be gathered would likely occur in the Warm Springs drainage, without surface water connectivity to the Salmon River, and where no stream habitat occupied by species of concern or native fish exist.

A portion of the wild horse gather activities under alternative 1 would occur in the Road Creek watershed on public lands, where unoccupied designated critical habitat for Chinook salmon occurs, and streams are known to be occupied by westslope cutthroat trout and rainbow trout (Table 17; Map 3). Occupied habitat in Road Creek downstream of the CHMA would not be influenced by gather operations, which would not occur nearby, because the pattern of horse presence is not known to result in their presence on private lands near the mouth. The majority of existing capture sites depicted on Map 3 occur away from perennial fish bearing streams, with substantial buffers to prevent effects to riparian areas, water, or fish habitat. Furthermore, horse gather operations include an SOP identified under Appendix B which establishes that *"the capture sites would be constructed so that no riparian vegetation is contained within them. No vehicles would be operated on riparian vegetation or on saturated soils associated with riparian/wetland areas."* Thus, all existing CHMA capture sites and potential additional sites would occur outside of active riparian zones (e.g. based on lateral extent of riparian vegetation). Most existing sites occur outside of riparian habitat conservation areas (RHCA), identified in the Challis RMP (P. 83-84, Attachment 4). These are categorized in the Challis RMP as: 1) a 300-foot buffer along perennial, fish bearing streams; 2) a 150-foot buffer along perennial non-fish bearing streams; 3) a 150-foot buffer around ponds, wetlands, lakes, reservoirs and wetlands greater than 1-acre is size; 4) and a 100-foot buffer around wetlands less than 1-acre and landslides / landslide prone areas (USDI-BLM, 1999b; USDI-BLM, 1995b). Gather personnel may need to establish additional capture sites, beyond those depicted on Map 3, based upon the locations of the horses at the time of the gather.

Under Alternative 1, a single sorting/holding facility would be established within or adjacent to the CHMA. There are three proposed locations where a single sorting/holding facility could be established to facilitate gather operations, fertility control, trailer-loading, and selective removal. One location is along the Spar Canyon Road ≈ 1.5 miles from the East Fork Salmon River, in an existing gravel pit resilient to impact which should preclude effects to fish or habitat associated

with the East Fork Salmon River. Temporary sorting/holding facilities would not extend beyond the road towards the Spar Canyon drainage, which does not support aquatic resources or riparian vegetation. The other locations, far from a fish bearing streams, occur in uplands on the Warm Springs side of the CHMA (Map 3). However, based on the distribution of wild horses during the proposed gather, implementation may require establishing a sorting/holding facility elsewhere in the CHMA. This would not result in effects to fisheries resources because any "new" locations would be established outside of the RHCA, and unlikely to even be proximal to a water body, and would not occur within the Road Creek watershed. Similarly, the Challis Horse Corrals would serve as preparation facility and is located in upland habitat ≈2.5 miles from the nearest fish bearing habitat in the mainstem Salmon River, and no surface water conveyance to the Salmon River occurs proximal to the corrals and thus no effects to fish or habitat in the mainstem Salmon River would occur.

There are three existing wild horse capture sites adjacent to Road Creek, which based on the location of the road and topography do occur within the RHCA (Map 3). One site is located just downstream of the confluence of Horse Basin Creek and another located on the road approximately 1/3 mile downstream of the Bear Creek confluence into Road Creek. Another capture site is located upstream of these, approximately one mile from the Bear Creek confluence. The most upstream capture site is outside of the RHCA on the Road Creek Road, near the North Fork Sage Road, between riparian DMAs RC-KA-03 and RC-KA-04. However, it is important to note that only one site in the Road Creek watershed is likely to be used during proposed horse gather operations. This is consistent with past gathers, including those in 2004 and 2009, when only one capture site in the entire Road Creek was used.

Holding horses within these capture sites would cause temporary localized impacts to upland vegetation from trampling as well as loosening of surface soil. No effects to substrate composition in Road Creek are expected because any potential sediment transport would be buffered by the existing road prism and both upland and riparian vegetation. Further, the proposed capture sites along Road Creek are used infrequently and post-gather impacts are not apparent and sites are not readily discernible. For example, persistent disturbance and increases of invasive weeds have not occurred. During the following spring / summer season minor impacts to upland vegetation and soils should be repairable upon regrowth of vegetation.

Chinook salmon or bull trout spawning and incubation does temporally align with fall-season gather activities, but only occurs in habitat outside or bordering the CHMA in Herd Creek, East Fork and mainstem Salmon River. No effects would occur because gather activities would not occur near them (e.g. capture sites and facilities are all greater than 1.5 miles from occupied habitat), and predominately fragmented ephemeral drainages throughout the CHMA and beaver impoundments and intermittent reaches in Road Creek preclude downstream indirect effects. Within Road Creek and its tributaries, October gather operations would not overlap with spring/summer spawning and egg incubation for westslope cutthroat trout or rainbow trout (USBWP 2005), where sedentary redds can be susceptible to trampling or other disturbance.

Under Alternative 1, it is anticipated that helicopter-assisted gathering of horses would primarily occur along upland trails and existing roads used by and familiar to wild horses, which is consistent with past wild horse gather operations. Based on the distribution of capture sites

relative to fish bearing streams in the Road Creek watershed and observations during past gathers, there is a low likelihood of a wild horse herd being "gathered" across a fish bearing stream. For example, during the 2009 wild horse gather, no horses were actively gathered across fish bearing streams, but 4 individuals were observed to deviate from the band and forded Road Creek after an unexpected vehicle ascended the road they were being gathered along. Because stream crossings by wild horses, resultant of gather operations, are expected to occur infrequently or not-at-all and capture site destination would be located within the CHMA interior where no listed fish species are known to occur in Road Creek or its tributaries, the horse gather operations in the proposed gather area would not affect Chinook salmon, steelhead, bull trout, or sockeye salmon or habitat. In the event some horses forded a fish bearing stream occupied by westslope cutthroat trout or rainbow trout, no effects to these individuals are expected. For example, if wild horses forded Road Creek or its tributaries, predominately dense woody vegetation along the streambanks and undercut banks would provide suitable escape cover from the threat individual or small groups of wild horses would present.

Under Alternative 1, it is anticipated that after gather operations the population would undergo a short term (≈3-5 years) reduction. This may result in an in kind short term reduction in horse use in uplands, at uplands springs / seeps and perennial stream reaches where horses have been observed to occur. Horse gather operations are the active management approach described in the Challis RMP and employed to maintain the AML. Effectiveness monitoring at DMAs and PIBO-EM sites in the Road Creek watershed can be used to assess effectiveness of management relative to PACFISH, INFISH, and Challis RMP objectives. For example, high bank stability (≥80%) and late-seral greenline vegetation currently predominate along fish bearing streams in the Road Creek watershed, and is well documented at the PIBO-EM site (Figure 1 and Table 14). Therefore the ongoing approach to management and the 2012 horse gather would not prevent attainment of PACFISH riparian objectives and would allow for continued maintenance or recovery of riparian vegetation, bank stability, and fish habitat associated with perennial fish bearings streams, Road Creek, Bear Creek and Mosquito Creek.

However there are localized riparian area reaches in the Road Creek watershed, at both upland springs and fish bearing stream reaches, where wild-horse use is known to be focused. Often these locations have apparent bank alteration, regardless of the wild horse herd being at or above AML, and in the absence of cattle use. For example, along lower Horse Basin Creek (within the cattle exclosure) wild horses use is relatively frequent, and decreased bank stability from utilization by horses would persist. Streambank alterations attributable to wild horses present along Road Creek occur relatively infrequently. During March 2012 visual observations along Road Creek at monitoring site RC-KA-02 where horse presence has been observed in past winter / spring seasons , indicated no signs of wild horse streambank impacts were apparent, with streambank ice shelves that would preclude impacts much of the winter and early spring. In addition, the relative difference in horse use along Horse Basin Creek and Road Creek is related to the general distribution of wild horses being strongly related to portion of the CHMA north of Road Creek. Because impacted reaches are not distributed widely in the watershed and maintenance of the AML is proposed, the pattern and intensity of wild horse use relative to fish bearing streams is unlikely to increase and thus proposed horse gather operation would not have an effect on fish habitat within the CHMA.

Alternative 2
The potential for environmental effects to threatened, endangered and sensitive fish and fisheries from horse gather operations under this alternative are related to population size and the extent of gather operations (e.g. captures sites within the RCHA associated with fish bearing streams). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 3, and 4 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to fish bearing streams and rivers would be the same under this alternative as alternative 1.

Alternative 3
The potential for environmental effects to threatened, endangered and sensitive fish and fisheries from horse gather operations under this alternative are related to population size and the extent of gather operations (e.g. captures sites within the RCHA associated with fish bearing streams). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 2, and 4 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to fish bearing streams and rivers would be the same under this alternative as alternative 1.

Alternative 4
The potential for environmental effects to threatened, endangered and sensitive fish and fisheries from horse gather operations under this alternative are related to population size and the extent of gather operations (e.g. captures sites within the RCHA associated with fish bearing streams). The post gather wild horse population as a result of this alternative would not differ from alternatives 1, 2, and 3 and any subsequent changes in population growth rate would not have a differentiable effect to riparian and wetlands resources over the 3 – 5 year time period prior to the next anticipated gather. The spatial and temporal extent of the gather operations relative to fish bearing streams and rivers would be the same under this alternative as alternative 1.

Alternative 5
Under this alternative, no horse gather activities would occur, and rather than a short term reduction of the horse population and maintenance of the AML (as described under alternatives 1-4), the horse population would continue to increase. Therefore increase of use by wild horses at riparian areas and upland springs is anticipated. This may cause intensified horse use at localized areas along fish bearing streams in the Road Creek watershed. For example, monitoring data indicates that when the AML is exceeded, wild horse effects (trampling, vegetation utilization, defection etc.) can intensify at riparian areas and upland springs. Grazing use criteria are used to manage the intensity of livestock grazing. Stubble height and total bank alteration criteria have been set for the perennial streams in the CHMA by the Challis RMP. Use of riparian areas by wild horses has resulted in use of livestock exceeding grazing standards. In 2003 there were 203 horses counted during the census and livestock grazed from 6/16-7/11; when livestock were done grazing at Horse Basin Creek Key Area 2 the stubble height was 4", on October 23 the stubble height was at 2" (the standard is 3" pursuant to the Challis RMP) and the bank shears were 26% (the Standard is less than 10% pursuant to the Challis RMP). In 2006, Horse Basin was rested from cattle grazing and 231 horses were counted during the census that

year, and a location known to receive focused wild horse use, stubble height was measured at Horse Basin Creek Key Area 2 at two inches. In both of these cases the grazing use criteria was exceeded and it was attributable to only horse use (see Appendix I). Based on patterns of wild horse use, under this alternative bank stability and greenline riparian vegetation important to instream fish habitat would be degraded along Horse Basin Creek where horses are known to concentrate relative to all other fish bearing habitats in the CHMA. This alternative may also result in changes in the spatial pattern of horse use and additional effects to unoccupied designated critical habitat for Chinook salmon and resident salmonids along Road Creek on BLM lands where wild horse use is relatively infrequent.

3.9 Wilderness Study Areas

3.9.1 Affected Environment

Approximately 47% of the CHMA is located within lands managed as WSAs (see Map 6). All 48,500 acres of the Corral-Horse Basin WSA fall within the CHMA. The Jerry Peak WSA makes up 46,150 acres; 23,269 acres of which are in the CHMA. WSAs are managed according to the Challis RMP and the Bureau's Manual 6330 – Management of Wilderness Study Areas (7/13/2012), and BLM pays careful and particular attention to proposals that could limit Congress' ability to designate areas as wilderness. The Manual directs that in a WSA the preservation of wilderness values within the WSA is paramount and should be the primary consideration when evaluating any action that may conflict with or be adverse to those wilderness values. Any proposed use or facility within a WSA must be evaluated to determine whether the action would impair wilderness values. The Manual states, "Wild horse and burro populations must be managed at appropriate management levels so as not to exceed the productive capacity of the habitat (as determined by available science and monitoring activities), to ensure a thriving natural ecological balance, and to prevent impairment of wilderness characteristics, watershed functions, and ecological processes. The BLM should limit population growth or remove excess animals as necessary to prevent the impairment of the WSA." (1.6.D.10). The BLM, therefore, considers proposals in the inventory area on a case-by-case basis to determine the potential impacts on wilderness characteristics.

As discussed above under the heading of *Relationship to Statutes, Regulations, Policy, Plans or Other Environmental Analysis*, the Manual provides guidance specific to wild horse and burro management which directs the BLM to manage populations at the appropriate management level to ensure a thriving natural ecological balance.

Wild horse census data from 1980 (the time of WSA designation) shows that 621 horses were counted on June 12th, 306 were gathered and removed from the CHMA in October, and 319 horses remained in December. The 1980 Intensive Wilderness Inventory does not include a narrative description of the wilderness characteristics for either the Corral-Horse Basin or Jerry Peak WSAs. The following is a synopsis of the characteristics as described in the 1991 Idaho Wilderness Study Report:

Corral-Horse Basin WSA:

Size and Physical Characteristics

The WSA contains 48,500 acres of BLM managed land roughly bounded on the north by Spar Canyon, on the west by the East Fork of the Salmon Road, on the south by Road Creek, and on the east by Dry Gulch Road. The WSA is composed of rolling hills surrounding Corral and Horse Basins. Anderson Peak, at 9,342 feet, dominates the WSA. The vegetation is predominantly sagebrush and grass with strips of timber on streams, sideslopes, and bottoms. There is one large stand of Douglas-fir on the east slope of Anderson Peak.

Naturalness

The Corral-Horse Basin WSA presents the visitor with a general appearance of naturalness. The majority of human imprints are grazing activities, fences, and waterhole developments. These imprints are not considered to be major impacts to naturalness and blend into the landscape when viewed from more than .5 mile. Impacts to the natural appearance of the WSA consist of two cherry-stem roads which breach the boundaries for 6 miles and two vehicle ways traversing the WSA on the east.

Solitude

Rolling hills, wide basins, lack of vegetative screening, and outside sights and sounds from the cherry stems, boundary roads, and private ranches all detract from the solitude of the WSA, despite the WSA's size.

Primitive and Unconfined Recreation

The relatively large size of the unit, lack of man-made or natural barriers, and lack of developments result in outstanding opportunities for primitive and unconfined recreation. Opportunities are available for hiking, backpacking, fishing, hunting, horseback riding, cross-country skiing, snowshoeing, photography, bird-watching, and sightseeing. The lack of barriers and rolling terrain also encourage off-road vehicle use, especially in the fall.

Supplemental values

The excellent opportunities for wild horse viewing were identified as special features for this WSA (USDI-BLM 1991).

Jerry Peak WSA:

Size and Physical Characteristics

The WSA contains 46,150 acres of BLM managed land roughly bounded on the south by the Challis National Forest, on the west by the East Fork of the Salmon Road, on the north by Road Creek, and on the east by Pecks Canyon Road. The WSA is composed of rolling hills with sagebrush and grass on the northern half of the unit while the southern portion has steeper terrain culminating with Jerry Peak (10,010 ft. elevation). Large areas of timber are located in the upper reaches of Bear, Mosquito, Sage, and Lake Creeks. Herd Lake, located in the southwest portion of the WSA is popular for fishing and sightseeing.

Naturalness

The Jerry Peak WSA presents the visitor with a general appearance of naturalness. The overall influence of human imprints on the naturalness of the area, as perceived by the

visitor, is minimal due to the wide dispersal and low impact developments. Imprints exist from fences and spring developments associated with range management, access roads, and jeep trails. Range improvements tend to be small and blend in with the natural landscape. The four dead-end roads (Herd Lake, Mosquito Creek, Sage Creek, and Bradshaw Creek), while not technically part of the WSA, influence the perception of naturalness.

Solitude
Topographic relief and vegetative screening, especially in the Bear Creek and Lake Creek drainages, provide for outstanding opportunities for solitude.

Primitive and Unconfined Recreation
Outstanding opportunities for primitive and unconfined recreation exist in this WSA due to the large size of the WSA, lack of barriers and developments in or near the eastern portion of the unit. Opportunities are available for hiking, backpacking, fishing, hunting, horseback riding, cross-country skiing, snowshoeing, photography, bird-watching, and sightseeing.

Supplemental values
Excellent opportunities for viewing wild horses and the landslide (which created Herd Lake) were identified as special features for this WSA (USDI-BLM 1991).

During the Challis BLM travel management planning effort from 2002-2009, historic aerial photo analysis and an intensive inventory review were performed to determine the presence of motorized vehicle routes in the WSAs. Any vehicle routes not present within the WSAs at the time of inventory were removed from consideration for designation, not included on the final travel maps, and remain closed to motorized vehicle use. All routes were analyzed; however, some of these routes were left open to motorized vehicle use and some routes were closed. Cross country travel by motorized or mechanized means is prohibited in all WSAs managed by the Challis Field Office, including the Corral-Horse Basin and Jerry Peak WSAs.

3.9.2 Environmental Effects

Proposed Action-Alternative 1
Wild horses were identified during the Corral-Horse Basin and Jerry Peak WSA inventory processes as a supplemental wilderness value within both of the WSAs. Appropriate management techniques identified in the Wilderness IMP have been built into each alternative. Each of the action alternatives would capture enough horses to reduce the herd size to the Appropriate Management Level (185 head). This alternative would also utilize identical capture site locations and gather techniques (helicopters for aerial herding, temporary capture sites, sorting/holding facilities and use of motorized vehicles only on routes which existed at the time of inventory and designated for vehicle use).

It is likely that during the gather there would be some amount of surface disturbance due to the concentration of horses and humans within a temporary capture area. This surface disturbance would primarily occur outside of WSA boundaries due to project designs incorporated for the protection of WSA values. Where surface disturbance does occur within the WSA boundaries it

would not be to a degree which requires reclamation. By maintaining the wild horse herd at the AML, degradation caused by overgrazing would be reduced — thus maintaining the overall health and appearance of the WSAs.

Nothing within the proposed action alternative would affect the size and physical characteristics of either the Corral-Horse Basin or Jerry Peak WSAs. Wilderness values such as outstanding opportunities for primitive recreation, solitude and naturalness would be temporarily impacted by the presence of human activity including helicopters, trucks, riders and temporary capture sites during the gather. The duration of the gather, and the impacts identified above, is expected to last about two weeks. The supplemental values noted in the original inventories include excellent wild horse viewing in Corral-Horse Basin WSA and the geological value of the Herd Lake landslide in Jerry Peak WSA. Wild horse viewing opportunities would be temporarily reduced due to fewer visible animals.

This project would be substantially unnoticeable once the temporary capture facilities are removed. These actions would not affect the area's wilderness characteristics or values in a manner which would constrain Congress' ability to determine suitability for preservation as wilderness. All of the action alternatives are consistent with the BLM Manual 6330 – Management of Wilderness Study Areas.

Alternative 2
Under this alternative effects would be similar to the proposed action alternative. It is anticipated that the effects of the gather (i.e. reduced wild horse numbers) would have a shorter lasting duration.

Alternative 3
Under this alternative effects would be similar to the proposed action alternative. It is anticipated that the effects of the gather (i.e. reduced wild horse numbers) would last for a longer duration of time. Adding geldings to the population may reduce or limit reproduction.

Alternative 4
Under this alternative effects would be similar to the proposed action alternative. It is anticipated that the effects of the gather (i.e. reduced wild horse numbers) would have a shorter duration of time.

Alternative 5
Under the No-action alternative, there would be no direct impacts to the wilderness characteristics of either the Jerry Peak or Corral-Horse Basin WSAs. However, indirect impacts would result from the unmanaged population growth of the wild horse herd. Effects to the soil, water, vegetation, wildlife and aesthetic qualities of the WSA would mount as the wild horse population continued to expand. This could ultimately impact the naturalness of the units and the outstanding opportunities for primitive and unconfined recreation. The No-action alternative would not be consistent with the Manual which states, "… the Bureau must still endeavor to make every effort not to allow populations within WSAs to degrade wilderness values, or vegetative cover as it existed on the date of the passage of FLPMA. Wild horse and burro

populations must be managed at appropriate management levels as determined by monitoring activities to ensure a thriving natural ecological balance."
(USDI-BLM, 1991)

3.10 Recreation

3.10.1 Affected Environment

The CHMA falls primarily within the Challis Extensive Recreation Management Area (ERMA), while a sliver along the East Fork and Main Salmon Rivers falls within the Upper Salmon River Special Recreation Management Area (SRMA). The Upper Salmon River SRMA attracts and concentrates substantial numbers of recreationists who come to the area due to the outstanding opportunities for river recreation, ease of access, international name recognition, and proximity of the area to other prominent recreation centers. The SRMA is managed to accommodate this concentration of use by providing developed recreation opportunities such as campgrounds, day use areas, trails, interpretive signage, and boating facilities. The majority of recreational use in the Main Salmon River corridor, and recreational developments, occur between highway 75 and the river. Along the East Fork Salmon River, most use occurs along the East Fork Road and at the Little Boulder Creek Recreation Site.

In contrast to an SRMA, recreation management within an ERMA is custodial in nature and is not the driving management factor in the area. Recreation in the ERMA is generally dispersed in nature and includes hunting, fishing, hiking, wildlife viewing, scenic driving, and off-highway vehicle (OHV) use. Dispersed recreation activities allow visitors to experience an area in an unstructured manner, remove themselves from every day pressures, and to challenge themselves in an outdoor setting. Benefits resulting from these experiential opportunities are many and include a closer relationship to the natural world, improved physical and mental health, and interpersonal connections with other people who enjoy similar experiences.

Elements of the physical, administrative, and social setting can have an impact on both the opportunities and benefits for recreationists to the area. Approximately 47% of the Challis CHMA is managed by the BLM as WSAs. In order to protect the wilderness characteristics of these areas, and to provide a non-motorized hunting experience, the BLM implemented annual seasonal motorized closures from October 1-December 31 in the Corral-Horse Basin and Jerry Peak WSAs. Herd Creek, Road Creek, North Fork of Sage Creek, and Spar Canyon Roads are the only routes available to motorized use during the seasonal closure period. Due to these administrative actions affecting the ERMA, recreationists visiting the WSAs during this period of time have an expectation of a primitive recreational opportunity unaffected by the presence of motorized vehicle use.

The gather is scheduled to occur in October which coincides with the commencement of big game rifle hunting seasons in this area (Idaho Department of Fish and Game Hunt Unit 36-A). In 2011, the following hunts took place in Unit 36-A during the month of October:

Table 18. October 2011 Hunts within Hunt Unit 36-A and Number of Hunters

Date	Hunt #/Description of Hunt	# of Hunters
9/25-10/24	#4037/Pronghorn, Controlled Tag	10
10/10-10/24	NA/Regular Deer, General Tag	Unlimited
10/10-10/31	NA/White-tailed Deer, General Tag	Unlimited
10/26-10/31	#1019/Regular Deer, Controlled Tag	230
10/1-10/31	#2010/Antlered Elk, Controlled Tag	58
10/1-10/31	#2161/Outfitter Allocated, Antlered Elk, Controlled Tag	3

Unit 36-A is 494,000 acres, of which the CHMA affects 154,150 acres of public lands. The portion of the CHMA, and Unit 36-A, which is managed under the seasonal motorized closure is 72,500 acres.

3.10.2 Environmental Effects

Proposed Action-Alternative 1

Under the Proposed Action alternative 1, impacts to recreation would be limited. Due to the timing of the proposed gather (October), the user group most likely to be affected are big game hunters. The largest impact is likely to be the presence of the helicopter as it circles the area, directing bands of wild horses toward the capture sites. A second, and less disrupting impact, would be the possible restriction to vehicle traffic along Road Creek Road in the event that one of three capture sites on Road Creek drainage are utilized.

The greatest impact to recreational use of the ERMA would be expected to be a result of the use of a helicopter to gather wild horses during hunting season. The helicopter is expected to be in the air 5-8 hours a day for up to 1-2 weeks during the middle to late October. The sights and sounds of a low flying helicopter in the air for a majority of the daylight hours would impact the opportunity for solitude for any visitor to the area, regardless of the purpose of the visit (hunting, hiking, camping, etc.). The impact on hunting opportunity, and more specifically hunting success, would be entirely situation specific. It is possible that a hunt could be spoiled if the helicopter is situated in such a manner as to drive big game away from a hunter's position. However, it is equally possible that the flight pattern of the helicopter could direct the game toward a hunter, thus improving the odds of success.

A second likely impact to recreational visitors to the area would be the potential of the Arrowhead capture site to block through traffic on Road Creek. Road Creek Road is one of two routes which connect from east to west between Highway 93 and the East Fork area. It is also one of just a handful of routes not affected by the seasonal motorized closures in place to protect wilderness values and to provide a non-motorized hunting experience in the WSAs. However, even if capture sites along Road Creek are utilized for the proposed gather, the impacts to recreational use should be minimal for the following reasons; 1) Road Creek Road is a through route, so access would be available from either end at all times, 2) the capture site would only be expected to be in place 3-7 days, and 3) when not actively in use (containing, or soon to contain gathered horses), the capture would be opened up to allow vehicle access along Road Creek Road.

Alternative 2
Under this alternative effects to recreation would be nearly identical to the Proposed Action. The duration of higher wild horse reproduction increases the frequency of the gather cycle.

Alternative 3
Under this alternative effects to recreation would be nearly identical to the Proposed Action. The duration of lower wild horse reproduction decreases the frequency of the gather cycle.

Alternative 4
Under this alternative effects to recreation would be nearly identical to the Proposed Action. The duration of higher wild horse reproduction increases the frequency of the gather cycle.

Alternative 5
Under the No-action alternative, there would be no direct impacts to recreational use of the area. However, indirect impacts would result from the unmanaged population growth of the wild horse herd. Effects to the soil, water, vegetation, wildlife and aesthetic qualities of the CHMA would mount as the wild horse population continued to expand. This could ultimately impact the desirability of the area for dispersed recreation activities such as hunting and camping. The ability of visitors to view wild horses would increase if the gather were to be deferred, though the condition of the landscape and of the horses themselves might equally impact the viewing experience.

3.11 Soils

3.11.1 Affected Environment
The Challis Field Office area has 190 mapped soil units (USDA-NRCS 2002); 72 of these soil units occur within the CHMA. The soils within the CHMA are shallow to very deep, gravelly to stony loams to clay loams derived from extrusive igneous rocks; some of these soils contain calcic horizons due to limestone deposits. Soils occurring at the higher elevations have a thick surface horizon (mollic); however, most are dry for at least half the growing season (aridic) (USDA-NRCS 2002).

The erosion hazard across most of the CHMA is slight to moderate (USDA-NRCS 2002); this indicates soils in the CHMA area are able to capture store and safely release nearly all precipitation, except during occasional high intensity thunderstorms or intense short-duration (1-2 days) spring snowmelt. In such cases, surface flow and sediment transportation into streams can be pronounced, particularly on very steep slopes (>60 %). An exception to this is the "badlands" soils mostly associated with Malm Gulch and Sand Hollow Allotments (domestic livestock grazing privileges have been relinquished on both allotments) which make up approximately 8% (≈ 13,764 Acres) of the HMA. These soils are Dawtonia-Frailton Complex (20-50% Slopes), Farvant-Badland-Gradco Complex (25-60% Slopes), Frailton-Dawtonia Complex (15-50% Slopes), Frailton-Gradco Complex 35-60% Slopes), and Gradco-Farvant Complex (30-60% Slopes); these soils are considered sensitive due to their highly erosive nature. All the soil types within the CHMA have rapid infiltration rates although some may have a clay or calcic horizon within 20 inches of the surface that may perch surface water (USDA-NRCS 2002).

Biological crusts are soil particles bound together by organic materials and are formed by living organisms and their by-products (USDA-NRCS 1997). In cool desert environments biological crusts generally increase water infiltration by acting as holding structures for water (USDI-BLM/USGS 2001). Biological soil crusts do occur within the CHMA, however the extent to which they are present is fairly limited and highly dispersed.

Ground cover is affected by the timing, duration, frequency, and intensity of grazing use. Domestic livestock grazing is controlled by the various grazing systems (numbers and kind of livestock, season of use, and number of AUMs) applied to the allotments within in the CHMA. Wild horse grazing is manipulated by controlling the population (the intensity of use) as the timing, duration and frequency of wild horse use is unmanaged.

Other factors impacting ground cover are outside of management control, such as climatic conditions resulting in annual variations in forage production. Climatic conditions (i.e. timing of precipitation and temperature) are primary factors determining the rate of photosynthesis and thus plant growth.

3.11.2 Environmental Effects

3.11.2.1 Alternative 1-4

Areas of heavy use occur around existing water sources such as springs, troughs, water gaps, salt licks, and areas providing cover or shade. The soils within and closely surrounding these areas receive heightened use as compared to surrounding areas and may, in some instances (e.g. areas of low soil moisture) show signs of soil compaction, erosion, and reduced productivity. These areas of decreased vegetation and litter cover are generally more susceptible to soil erosion and increased runoff. Conversely, congregation areas with high soil moisture that undergo several freeze-thaw cycles each year are less likely to remain compacted. This freeze-thaw action promotes soil stability by decreasing compaction and increasing surface area and sites for seed germination and vegetative establishment.

Impacts to the soil resource from large ungulate grazing activities include compaction (Wheeler 2002) and disruption or destruction of physical or micro-biotic soil crusts (Memmott 1998), which can result in soil erosion. Surface disturbance that disrupts or destroys physical or micro-biotic soil crusts can also lead to erosion. Erosion of the soil surface following disturbances would remove the litter layer and potentially portions of the A horizon (the uppermost, organic soil layer). Of the entire soil profile, the litter layer and the A horizon contain the greatest amount of organic matter which is the source of plant-available nutrients (Neff 2005). Alterations to the nutrient cycle via erosion can reduce plant community productivity and create conditions that are conducive to the introduction of nonnative species (Kourtev 2002). Impacts, which are generally caused by hoofing action, would be greatest in high use areas such as water troughs, fence lines, and crossings. However, the majority of the soil surface would be stabilized by root mass, organic matter (e.g., herbaceous/woody litter, manure from domestic livestock, wild horses and wildlife), decomposition products, and/or biological crust.

Impacts directly related to the gather operation are likely to be limited to the capture sites and the sorting facilities. Most of the capture sites and sorting facilities are located in areas that were used in previous gathers and are already disturbed sites. Any additional or new capture sites necessary to facilitate a more efficient and safer gather would be cleared prior to placement, and would only be set up on existing roads so new disturbances would be minimal. The existing capture sites are located in areas where little or no biological soil crust occur, however the potential exists for disturbance to soil crusts to occur during the course of moving the wild horses to the capture sites. This could result in an increase in the erosive potential on a site by site basis as the soil holding and precipitation infiltration benefits that biological crusts provide could be reduced (Brotherson and Rushforth. 1983).

Immediately following the gather the horse population would have a short term reduction and this would likely result in a short term reduction in the intensity of horse use at areas of concentrated use, however as this is only a short term decrease in the population no substantial improvement in soil condition (compaction, infiltration ability, etc.) is expected to occur.

3.11.2.2Alternative 5

Under this alternative, the number of wild horses would increase leading to a potential increase and intensify of horse use across the CHMA. Of concern would be areas where concentrated use already occurs, where use would be intensified, and the possibility for initiating new areas of concentrated use. Population estimates have the herd size growing to 1,630 horses over the next 10 years, which equates to 19,560 AUM's. Both the projected wild horse numbers and projected AUMs are substantially over the designated herd size of 185 horses or 2,220 AUM's. At areas of concentrated use this increase could lead to reduction of cover which could increase soil erosion on a site by site basis. Land areas covered by plant biomass, living or dead, are protected and experience reduced soil erosion because raindrop and wind energy is dissipated by the biomass layer (Pimentel and Kounang 1998). Impacts to biological soil crusts would likely increase if the deferral is for an extended period of time and could lead to an increase in the erosion potential of the soil on a site by site basis.

3.12 Threatened/Endangered/Sensitive animals/birds/wildlife

3.12.1 Affected Environment

Threatened, Endangered, Candidate and Special Status Species

There are four terrestrial wildlife species that are identified by USFWS for consideration under Endangered Species Act (ESA) that have been documented or have the potential to occur in the CFO (Table 19).

Table 19. Threatened, Endangered, and Candidate Present on Lands Administered by the CFO.			
Common Name	**Scientific Name**	**Status**	**General Habitat**
Canada lynx	*Lynx canadensis*	Threatened	Conifer
Wolverine	*Gulo gulo luscus*	Candidate	Alpine, boreal, and arctic habitats
Yellow-billed cuckoo	*Coccyzus americanus*	Candidate	Riparian
Greater sage grouse	*Centrocercus urophasianus*	Candidate	Sagebrush steppe

The CHMA is not within a designated Canada Lynx (*Lynx canadensis*) Analysis Unit (LAU). A portion of lynx linkage exists on the southeast portion of the CHMA.

Wolverines (*Gulo gulo luscus*) seek higher altitude, colder habitats with persistent spring snow during denning and for physiological reasons the rest of the year. No designated habitat for wolverines exists within the CHMA.

Suitable yellow-billed cuckoo breeding habitat is defined as needing "large blocks of riparian..." with "dense understory foliage" (USFWS 2001). Likewise, Reynolds and Hinckley (2005) define breeding habitat requirements as "a minimum of approximately five acres of *prime* riparian habitat…of old growth cottonwoods, with a dense understory of willow or dogwood" (*emphasis added*). Reynolds and Hinckley (2005) conducted both a review of historic records and site sampling in Idaho, and concluded: 1) "yellow-billed cuckoos have never been particularly abundant in Idaho," and 2) the nesting strongholds are limited and few with "the statewide nesting population at fewer than 20 pairs, and in all likelihood closer to 10 pairs in an average year." Based on data from the USFWS (2001) and Reynolds and Hinckley (2005), potential, suitable breeding habitats do not exist in the CHMA for the yellow-billed cuckoo.

The Canada lynx, wolverine, and yellow-billed cuckoo would not be discussed further in this document due to a lack of suitable habitat and/or the lack of any known presence within the lands encompassed by the CHMA.

Greater Sage-Grouse

In response to declines in Greater sage-grouse populations, the *National Sage-grouse Habitat Conservation Strategy* (National Assessment) was developed to assess "the ecological status and potential factors that influenced greater sage-grouse and sagebrush habitats across their entire distribution" (Connelly 2004). The same year BLM developed the *National Sage-grouse Habitat Conservation Strategy* (National Assessment) "to guide future actions for conserving sage-grouse and associated sagebrush habitats and to enhance BLM's ongoing conservation efforts" with the purpose "to set goals and objectives, assemble guidance and resource materials, and provide a comprehensive management direction for the BLM's contributions to the on-going multi-state sage-grouse conservation effort in cooperation with the WAFWA" (USDI-BLM 2004b). In Idaho, state-wide guidance is provided by the *Conservation Plan for the*

Greater Sage-grouse in Idaho (Idaho Sage-grouse Advisory Committee 2006). The primary goal of the plan is to:

> "Maintain, improve, and where possible increase, sage-grouse population and habitats in Idaho, while considering the predictability and long-term sustainability of a variety of other land uses."

In order to meet this goal, the plan outlines a series of conservation measures designed to minimize impacts associated with a wide array of potential threats to sage-grouse and their habitats.

The Idaho Sage-grouse Management Plan was completed in 1997. This plan called for the "creation of Local Working Groups (LWG) that would develop sage-grouse management plans for each of Idaho's sage-grouse planning areas" (Idaho Sage-grouse Advisory Committee 2006). The Challis Sage-grouse Local Working Group (Challis LWG) was formed in 2002. The Challis LWG is made up of interested parties; both private citizens and public agencies. The Challis LWG completed the Challis Sage-grouse Conservation Plan (Challis SCP) in 2007. The goal of Challis SCP is to plan and oversee the implementation of conservation measures within the Challis Sage-grouse Planning Area "that will result in stable, healthy sage-grouse population within sustainable habitats" and that "management should occur in a socially, economically, and ecologically focused manner" (CSGLWG 2007). The Challis Sage Grouse LWG designated priority areas within the Challis SCP and has mapped seasonal sage-grouse habitat throughout the LWG area. Seasonal habitat is delineated by sage-grouse observations and habitat type encompassing those locations. Seasonal maps are updated as new data points are collected.

On March 5, 2010, the USFWS (FWS) found the greater sage-grouse "warranted, but precluded by higher priority listing actions" and placed it on the Candidate species list. Until sage-grouse can be addressed by USFWS, it is managed by the state and addressed by BLM as a special status species (USDI-BLM 2008b). In response to the petition to list, the FWS identified habitat conversion and fragmentation from wildfire, invasive plants, energy and infrastructure development, urbanization, and agricultural conversion to be the primary threats to greater sage-grouse throughout its range. Through the development of planning strategies to address FWS concerns for "improved regulatory mechanisms", BLM has identified wildfire, habitat loss due to invasive plant species, and habitat fragmentation as the major threats in the western portion of the existing sage-grouse range, of which Idaho is part.

On December 27, 2011, the BLM released Instruction Memorandum No. 2012-043, Greater Sage-grouse Interim Management Policies and Procedures (Interim Management), to provide interim conservation policies and procedures to be applied to ongoing and proposed authorizations and activities that affect the Greater Sage-grouse and its habitat until long term conservation measures can be incorporated into Land Use Plans. These policies and procedures apply to Preliminary Priority Habitats (PPH) and Preliminary General Habitats (PGH). PPH is defined as "areas that have been identified as having the highest conservation value to maintain sustainable Greater Sage-Grouse populations" and PGH is defined as areas "of occupied seasonal or year-round habitat outside of priority habitat." The majority of the CHMA is identified PPH (~124,119 acres) by Interim Management. The remainder of the CHMA is considered PGH

(~43,468 acres) except for two small portions (~261 acres for both) on the southern end of the CHMA that are not identified as either PPH or PGH (see Map 4). For PPH, policies and procedures are "to maintain, enhance, or restore conditions for Greater Sage-grouse and its habitat" (USDI-BLM 2011b). Specifics to wild horse and burro management from the policies and procedures include "Manage wild horse and burro population levels within established Appropriate Management Levels (AML)."

Sage-grouse habitat, which consists of large expanses of sagebrush-dominated shrub steppe, was delineated cooperatively by the BLM, IDFG, and other partners during the development of the *Conservation Plan for the Greater Sage-grouse in Idaho* (Idaho Sage-grouse Advisory Committee 2006). The majority of public lands administered by the Challis Field Office, including the CHMA, are designated as "key" sage grouse habitat. Key sage-grouse habitat is defined as "areas of generally intact sagebrush that provides sage-grouse habitat during some portion of the year" (Idaho Sage-grouse Advisory Committee 2006).

It is estimated that greater sage-grouse range wide distribution in potential habitat pre-settlement was 1,200,483 km^2 and current distribution is 668,412 km^2 (Connelly 2004). The CHMA and the Big Lost Valley in general represent a portion of the Big Lost sage-grouse sub-population which takes in 550,791 acres of the Warm Spring and Big Lost watersheds. Lek count data presented by Garton et al. (2011:348), suggests that this subpopulation has declined from an estimated high of 22,000 males in 1969 to approximately 5,500 males in 2007. The subpopulation appears to have stabilized at around 5,000 males since 1992. In comparison the National Assessment states:

> "Annual rates of change suggest a long term decline for greater sage-grouse in western North America and support the trend information obtained from lek attendance (males/lek) data. Sage-grouse populations declined at an overall rate of 2.0% per year from 1965 to 2003. From 1965-85, the population declined at an average of 3.5%. From 1986 to 2003, the population declined at a lower rate of 0.4% and fluctuated around a level that was 5% lower than the 2003 population (Connelly 2004)."

Beever noted in Studies of Avian Biology, Greater Sage-grouse: ecology and conservation of a landscape species and its habitats (2011) that "Past research elaborated that free-roaming horses can exert notable influences in sagebrush (*Artemisia spp.)* communities, on structure and composition of vegetation and soils, as well as indirect influences on numerous animal groups whose abundance collectively may indicate the ecological integrity of such communities."

Pygmy Rabbit

Pygmy rabbits (*Brachylagus idahoensis*) are known to be distributed historically (Green 1980) and presently (BLM files) throughout southern and eastern Idaho where preferred habitat conditions exist. Pygmy rabbits are sagebrush obligates and are found in landscapes with tall, dense stands of sagebrush and deep soils for construction of burrow systems (Green 1980). On September 20, 2010, the USFWS 12-month finding on the petition to list found pygmy rabbits

"not warranted at this time" for the populations found outside the Columbia River distinct populations segment.

Migratory Birds

Migratory birds have the potential to exist throughout the CHMA on all habitat types. The majority of wild horse use takes place in shrub steppe habitat and riparian corridors. Fragmentation and removal of habitat has been shown to have impacts on the presence of sagebrush obligate passerine species (Knick and Rotenberry 1995). Potential impacts to migratory birds are; direct disturbance, and removal of potential nesting habitat.

Big Game Species

Gray Wolf

Wolf populations have grown from the initial release of 66 wolves within the Intermountain West in 1995 and 1996 to an estimated 705 by the end of 2010 in Idaho alone (Holyan et al. 2011). Gray wolf management and population control efforts have been conducted in response to livestock depredation problems under the Memorandum of Agreement between The Secretary of the Interior and The State of Idaho (dated January 5, 2006), and in accordance with Idaho Wolf Population Management Plan (IDFG 2008). Idaho Department of Fish & Game conducted a hunt for wolves following the initial wolf delisting by USFWS in which 173 were harvested. Recorded wolf mortalities, including control efforts, have ranged from 15 wolves being removed in 2003 to 273 in 2009. On May 5, 2011, the USFWS, as directed by legislative language in the fiscal year 2011 appropriations bill, reinstated the 2009 rule removing gray wolves in the Northern Rocky Mountains Distinct Population Segment, which included the state of Idaho, from the endangered species list. Recreational hunting began in 2011 in the hunting unit on and around the CHMA with a quota limit that can be taken by recreationists. The quota for each hunting unit would be adjusted as needed to meet the management goals in IDFG's Idaho Wolf Population Management Plan. The Castle Peak Pack territory overlaps with the CHMA. Individuals not associated with a pack can be present throughout the CHMA. Potential impacts to gray wolf would be through direct disturbance and indirectly through removal of a potential food source.

Other Big Game

The Challis Field Office RMP designates habitat for antelope, bighorn sheep, elk and mule deer within the CHMA. These species would be referred to collectively as Big Game in this section. Of most concern are areas considered for winter use, especially those that have been designated as "crucial winter range." These crucial winter range areas are those that are the most readily accessible to big game and utilized most often in a severe winter. Potential impacts to big game would be displacement and vegetation removal.

Table 20 Current designated big game winter ranges within the CHMA:

Table 20. Acres of Winter or Crucial winter Range by big game species:		
Species	Winter Range	Crucial Winter Range
Mule deer (*Odocoileus hemionus*)	67,563	15,713
Elk (*Cervus elaphus*)	54,254	3,360
Pronghorn Antelope (*Antilocapra americana*)	24,314	11,101
Bighorn Sheep (*Ovis canadensis*)	61	51
*Acreages Assessed in GIS		

3.12.2 Wildlife Environmental Effects

Alternatives 1-4
Threatened, Endangered, Candidate and Special Status Species

Greater Sage-Grouse

Potential impacts to sage-grouse would be disturbance of individuals by gathering activities and vegetation removal at capture sites. Disturbances by gathering activities would be short term and would be confined to small portions of the CHMA leaving the rest of the CHMA available for use without such disturbances. Capture sites would be temporary, limiting the time that horses would be present within them. Vegetation removal at capture sites is rarely entire and the percent of vegetation removal is dependent on time and intensity of activity at each site. Vegetation damage is likely, but is limited to a very small area (<0.01%) within the CHMA. Vegetation removal creates potential sites for invasive weeds to establish. SOPs (Appendix B) for horse gathers are to monitor these sites for weeds and treat if they are found. Several of the capture sites have been used for past gathers and remain weed free and not visually apparent. The gather would be performed at a time when there would be no lekking or nesting and young of the year chicks would already be capable of flight.

Pygmy Rabbit

Pygmy rabbits have the potential to be present throughout the CHMA where their preferred habitat exists. Potential impacts to pygmy rabbits would be vegetation removal at occupied burrows. SOP's for capture site placement is that it would be placed as to cause "as little damage to the natural resources of the area, as possible" and would have to be approved by an Authorized Officer. The Authorized Officer would be trained in recognition of pygmy rabbit sign so as to avoid capture placement on burrows. Alternatives 1-4, would be in compliance with BLM Manual 6840 and would not lead to the listing of the species.

Migratory Birds

Horse gather activities would take place after nesting of migratory birds, eliminating impacts associated with these activities. Gathering activities would still have the possibility of disturbing individuals. Adult and healthy young of the year would be capable of flight. Gather activities would be short term and limited to a portion of the CHMA. The remainder of the CHMA and surrounding landscape would be available for use by individuals that might be disturbed. Any

disturbances to vegetation would be limited to capture and staging sites. SOP's would be used to limit vegetation disturbance by gather activities to previously disturbed sites or locate new sites in areas to cause as little resource damage as possible. Individual birds that might be using activity sites would have the surrounding habitat to relocate to. Alternatives 1-4, would be in compliance with BLM Manual 6840 and would not lead to the listing of the species.

Big Game Species

Gray Wolf

Gray Wolves are a highly mobile species capable of using habitat at a landscape scale. Wolves that might be present in the CHMA could be disturbed by gather activities. This would be short term and habitat impacted by gather activities would be available to wolves following those activities. The horse gather would reduce herd size and remove potential prey for wolves. Wolves have not been documented preying on horses within the CHMA. Additionally, cow elk herd numbers are meeting population objectives for hunt units within and around the CHMA. Alternatives 1-4, would be in compliance with BLM Manual 6840 and would not lead to the re-listing of the species.

Other Big Game

Impacts from gather activities would take place outside of the crucial winter period for big game eliminating the potential for disturbances during this sensitive time. Disturbances to big game present within the CHMA during the gather would be short term and limited to isolated areas. The remainder of the CHMA and the surrounding habitat would be available for use by big game that could be disturbed by gather activities. Vegetation disturbances would be limited to capture and staging sites. There are 8 possible capture sites located in designated mule deer winter habitat and 7 possible capture sites in elk winter (see Map 5). There are no possible capture sites located in antelope or bighorn sheep winter range and no possible traps sits located in crucial winter range for any of the big game species. To the extent possible these sites would be placed in previously disturbed sites and would represent a small portion of the CHMA. Potential vegetation damage from this alternative would be of a scale as not to be a factor in big game herd health.

Alternative 5
Threatened, Endangered, Candidate and Special Status Species

Greater Sage-Grouse

The AML would continue to be exceeded, if horses were not gathered under Alternative 5. "Long-term conservation objectives should consider the appropriate management levels of horses and burros that can be maintained, because free-roaming equids can influence the structure and function of sagebrush ecosystems" (Conelly, 2011). The horse herd has exceeded the AML and is consuming more AUM's than is set aside for them within the Challis RMP, and is leading to indirect effects of a reduction of nesting and brooding success for sage-grouse. Riparian areas are important to sage-grouse brood rearing. Ungulate utilization beyond that

allocated within the RMP would lead to increased impacts to riparian areas and increased potential for invasive weed infestations in areas of focused utilization such as riparian areas.

Pygmy Rabbit

Increased forage consumption by a larger horse herd could lead to a decrease in competition of grasses and forbs with sagebrush. An increase in sagebrush would favor pygmy rabbits in areas where burrow construction is possible. However, incidences of this would be scattered and small in scope of the CHMA. If horse herd numbers were to grow to the point of damaging mature sagebrush, individual pygmy rabbits could be impacted. Wild horse herd numbers in a magnitude to have an impact on sagebrush and indirectly on the pygmy rabbit population throughout the majority of the CHMA is not likely within the 10-year scope of Alternative 5. This alternative would be in compliance with BLM Manual 6840 and would not lead to the listing of pygmy rabbits.

Migratory Birds

An increased horse herd has a higher potential for impacts to nesting migratory birds. Whether or not the horse herd could grow to a size to have a measurable impact on nest success within the CHMA during the ten year period of this alternative is not known. If wild horse herd size were to increase to the point of having measurable impacts to migratory birds, they would be sporadic, both spatially and temporally, within the CHMA. The impacts would not exclude migratory bird use within the CHMA. The CHMA only occupies a portion (21%) of the CFO. CFO lands outside of the CHMA would be available for use by migratory birds without the wild horse herd being present. For these reasons, Alternative 5, would be in compliance with BLM Manual 6840 and would not lead to the listing of migratory birds.

Big Game Species

Gray Wolf

Greater forage consumption by horses in the CHMA would lead to greater competition with native ungulates, the wolves' primary prey. This could lead to a decreased native prey species. Horses could replace native ungulates as the preferred prey species of wolves who utilize the CHMA as a territory. This alternative would be in compliance with BLM Manual 6840 and would not lead to the re-listing of wolves.

Other Big Game

Utilization of forage by horses beyond what is authorized in the Challis RMP would be in direct competition with other authorized ungulate forage utilization. Big game forage utilization would likely shift to areas outside of the CHMA. This would lead to increased completion in big game areas outside of the CHMA. It could also lead to degradation of winter and crucial winter big game within and along the border of the CHMA.

3.13 Tribal Treaty Rights

3.13.1 Affected Environment

The 1868 Fort Bridger Treaty between the United States and the Shoshone and Bannock Tribes reserves the Tribes' right to hunt, fish, gather, and exercise other traditional uses and practices on unoccupied federal lands. The federal government has a unique trust relationship with federally-recognized American Indian Tribes including the Shoshone-Bannock Tribes. BLM has a responsibility and obligation to consider and consult on potential effects to natural resources related to the Tribes' treaty rights or cultural use. Resources or issues of interest to the Tribes that could have a bearing on their traditional use and/or treaty rights include: tribal historic and archaeological sites, sacred sites and traditional cultural properties, traditional use sites, water, fisheries, traditional use plant and animal species, vegetation (including noxious and invasive, non-native species), air and water quality, wildlife, access to lands and continued availability of traditional resources, land status, and the visual quality of the environment.

The CHMA includes unoccupied federal lands, Idaho State lands, and private lands located within the Shoshone-Bannock Tribes' aboriginal territory. Therefore, tribal treaty rights, as defined, are applicable to the project area. The current condition and nature of specific affected resources associated with tribal rights and interests are described in the following sections: Vegetation, Wildlife, and Fisheries.

3.13.2 Tribal Treaty Rights Environmental Effects

3.13.2.1 Alternatives 1-5

There would be no changes in land status or access associated with the proposed actions and the project area would retain its unoccupied Federal land status. During the actual wild horse gather, short term access limitations might be instituted to protect the health and safety of the horses, BLM employees and contractors. Information about where daily activities are expected to take place would be made available via a Wild Horse Gather Information Phone Line. Limitations would be expected to take place in specific areas for no more than 4-8 working days over no more than a 14 day period.

Discussion of potential impacts to specific resources associated with Tribal rights and interests can be found in the Vegetation, Wildlife, and Fisheries sections of this document.

3.14 Human Health and Safety

3.14.1 Affected Environment

Members of the public can inadvertently wander into areas that put them in the path of wild horses that are being herded or handled during the gather operations, creating the potential for injury to wild horses and to the BLM employees and contractors conducting the gather and/or handling the horses as well as to the public themselves. Because these horses are wild animals, there is always the potential for injury when humans get too close or inadvertently get in the way of gather activities.

The helicopter work is done at various heights above the ground, from as little as 10-15 feet (when herding the animals the last short distance to the capture site) to several hundred feet (when doing a reconnaissance of the area). While helicopters are highly maneuverable and the pilots are very skilled in their operation, unknown and unexpected obstacles in their path can impact their ability to react in time to avoid members of the public in their path. These same unknown and unexpected obstacles can impact wild horses being herded by the helicopter in that they may not be able to react and can be potentially harmed or caused to flee which can lead to injury and additional stress. When the helicopter is working close to the ground, the rotor wash of the helicopter is a safety concern by potentially causing loose vegetation, dirt, and other objects to fly through the air which can strike or land on anyone in close proximity as well as cause decreased vision. Though rare, helicopter crashes and hard landings can and have occurred (approximately 10) over the last 30+ years while conducting wild horse and burro gathers which necessitates the need to follow gather operations and visitor protocols at every wild horse and burro gather to assure safety of all people and animals involved. Flying debris caused by a helicopter incident poses a safety concern to BLM and contractor staff, visitors, and the wild horses.

During the herding process, wild horses would try to flee if they perceive that something or someone suddenly blocks or crosses their path. Fleeing horses can go through wire fences, traverse unstable terrain, and go through areas that they normally don‘t travel in order to get away, all of which can lead them to injure people by striking or trampling them if they are in the animal‘s path.

Disturbances in and around the capture sites and sorting/holding have the potential to injure the government and contractor staff who are trying to sort, move and care for wild horses by causing them to be kicked, struck, and possibly trampled by the animals trying to flee. Such disturbances also have the potential for similar harm to the public themselves.

The BLM is committed to allowing access by interested members of the public to the fullest possible degree without compromising safety or the success of operations. To minimize risks to the public from helicopter operations, the gather Contractor is required to conduct all helicopter operations in a safe manner, and to comply with FAA regulations (FAR) 91.119 (Appendix G) and BLM IM No. 2010-164 (Appendix D). Public observations sites would also be established in locations that reduce safety risks to the public (e.g., from helicopter-related debris or from the rare helicopter crash landing, or from the potential path of gathered horses), to wild horses (e.g., by ensuring observers would not be in the line of vision of horses being moved to the capture site) and to contractors and BLM employees who must remain focused on the gather operations and the health and well-being of the wild horses. The Visitor Protocol and Ground Rules for public observation found in Appendix E provide the public with the opportunity to safely observe the gather operations. Every attempt would be made to identify observation site(s) at the gather location that offers good viewing opportunities, although there may be circumstances (flat terrain, limited vegetative cover, private lands, etc.) that require viewing locations to be at greater distances from the capture site to ensure safe gather operations.

At recent gathers, public observers have ranged in number from only a handful of individuals to a maximum of between 15-25 members of the public. At these numbers, BLM has determined

that the current level of public visitation to gather operations falls below the threshold of an open air assembly under the FAR regulations. 14 CFR § 91.119.

At current populations, wild horses are moving across Highways 93 and 75. This presents a safety hazard to both wild horses and motorists. A number of collisions have been reported on Highway 75.

3.14.2 Environmental Effects

3.14.2.1 Alternatives 1-4

All helicopter operations must be in compliance with FAR 91.119. Public safety as well as that of the BLM and contractor staff is always a concern during the gather operations and is addressed through the implementation of Visitor and Ground Rules that have been used in recent gathers to ensure that the public remains at a safe distance and does not impede gather operations. Appropriate BLM staffing (public affair specialists and law enforcement officers) would be present to assure compliance with visitation protocols at the site. These measures minimize the risks to the health and safety of the public, BLM staff and contractors, and to the wild horses themselves during the gather operations.

Gathering wild horses that occur near the highway corridors would reduce the risk of motorist/wild horse collisions.

3.14.2.2 Alternative 5

There would be no gather related safety concerns for BLM employees, contractors or the general public as no gather activities would occur.

3.15 SocioEconomics

3.15.1 Affected Environment

The CHMA is located in Central Idaho within Custer County, which is among the most rural communities in the United States; it comprises approximately 3,160,320 acres with a total population of 4,368 with 0.9 persons per square mile. The population of Custer County grew by 0.6 percent between 2000 and 2010. The median age is 47 years old with 53 percent males and 47 percent females. The dominant areas of employment in Custer County are management and professionals at 35 percent; sales and office occupations at 20 percent; construction, extraction, and maintenance at 17 percent; service 13 percent; production/transportation 10 percent; and farming, fishing and forestry 5 percent. The unemployment rate in Custer County is currently 10.2 percent. The median household income is $41,910.00. Nearly 14 percent of the population lives below the poverty line. 93 percent of the population has a high school education (United States Department of Commerce 2010).

3.15.2 Environmental Effects

3.15.2.1 Alternatives 1-4

Gather operations are so transient in nature, only being within Custer County for less than a month, BLM does not anticipate direct socio-economic impacts would be measurable. However,

indirect impacts may result from impacts to other economic features. Timing of gather operations during hunting seasons may adversely affect or displace hunters which bring direct revenue stream into the local economy (i.e. spending on lodging, fuel, food, supplies, licenses, and other indirect expenditures). These same opportunities for local revenue may be replaced by the contractors and additional BLM staff that would be residing in Challis during the gather.

The CHMA contains a number of County and BLM roads. Travelers in the area may experience a short increase in area traffic due to gather operations, and small delays in traffic to allow for fueling of helicopters, and other gather operations.

3.15.2.2 Alternative 5

While the effects described under Alternatives 1-4 above would not occur under the No Action Alternative other economic impacts may develop. If wild horses were not gathered for a period of ten years or more, this action or lack of action could necessitate livestock being reduced or removed from allotments within the CHMA. Without federal land grazing, it would be difficult for any of the 10 livestock operators to remain viable operations. Custer County livestock operators depend on public land grazing because 97% of the county is Federal or state lands. Therefore, private land for leasing is difficult to find. If they were able to stay in the livestock industry it would be at a greatly reduced level.

As rangeland health deteriorates wildlife species including upland and big game numbers would suffer, thus limiting tags, hunting opportunity and harvest. These reductions would affect the number of hunters that would purchase goods within the county. This also would directly affect the outfitters and guides within the area.

4.0 Cumulative Impact Analysis For All Alternatives

NEPA regulations define cumulative impacts as impacts on the environment that result from the incremental impact of the Proposed Action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such actions (40 CFR 1508.7). Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. The time frame for analysis is from the passage of the Wild Free-Roaming Horses and Burros Act of 1971 to 2022 ten years past the proposed gather which is a reasonable time frame to consider potential future actions within this analysis.

The Cumulative Impacts Assessment Area (CIAA) for this project includes the CHMA; Bradbury Flat, Bradshaw Basin, Mountain Springs, Road Creek, Split Hoof, Willow Creek, and Warm Springs livestock grazing allotments in their entirety; and portions of the Sage Creek and Herd Creek allotments; Malm Gulch/Germer Basin, Lone Bird, Antelope Flat, East Fork Salmon River Bench and Sand Hollow ACEC's; and all of Jerry Peak West and Corral/Horse Basin WSA's; and sage grouse habitat connected to the CHMA (see Map 7). Landscape characteristics within the CIAA are consistent with those described in the Affected Environment for the CHMA.

The CIAA intersects four watersheds, East Fork Salmon River, mainstem Salmon River, Big Lost River, and Warm Springs Creek. Warm Spring Creek is fully allocated for irrigation and is influenced by geothermal springs and does not contain a native fish assemblage and was likely

historically inaccessible to listed salmonids in the Salmon River, and is not designated critical habitat. The tributaries to Warm Spring within the CIAA are disconnected from Warm Spring Creek and only convey water during intense precipitation and or high snow melt events. Warm Springs Creek is anthropogenically altered by a combination of existing roads, extensive land conversion for agriculture, and diversion arrays and channel networks utilized primarily in the Round Valley of Challis, ID. Consequently these streams have little potential to convey water or sediment to the Salmon River, or result in contributions discernible from background conditions.

A portion of the Big Lost Watershed is located in the southeastern part of the CIAA and consists primarily of the Sage Creek drainage. Sage Creek does not flow perennial along its entire reach, it typically sinks near the canyon mouth where hydric species terminate approximately 4.5 miles upstream of the ephemeral confluence into Chilly Slough. The Sage Creek drainage tributaries consist of North Fork Sage Creek, Bradshaw Creek, Corral Creek, and the South Fork of Sage Creek. The Sage Creek subwatershed does not contain a fish population (native or introduced) and was likely historically inaccessible by native fish assemblages in the Big Lost River. The Big Lost River watershed does not contain ESA listed salmon or trout, but does contain the Big Lost River whitefish, a candidate species for listing under ESA. Their distribution is limited to mainstem reaches and perennial tributaries in the upper watershed outside of the CIAA.

Road Creek drainage is described under the Affected Environment for Wetlands/Riparian Zones, Water Quality, and Threatened, Endangered, and Sensitive Fish; Fisheries because it is entirely contained within the CHMA.

4.1 Past and Present Actions

According to the 1994 BLM Guidelines for Assessing and Documenting Cumulative Impacts, the cumulative analysis should be focused on those issues and resource values identified during scoping that are of major importance. Accordingly, the issues of major importance identified are Livestock Grazing and Mining/Infrastructure Development.

Past, present, and reasonably foreseeable actions that have impacted the watershed to varying degrees include livestock grazing and mining/infrastructure development. Although these actions probably do not account for all of the impacts that have or are likely to occur in the watershed, GIS analysis, agency records, and professional judgment suggest that they have contributed to the vast majority of cumulative impacts that have occurred in the CIAA.

Table 21. Past, Present, and Reasonably Foreseeable Future Actions within the Pahsimeroi River Watershed.		
Type of Activity	**Past and Present**	**Reasonably foreseeable**
Livestock Grazing		
Number of Permits/Leases	BLM-15 active permits USFS-2 active permits State-8 leases	BLM- renewing/modifying grazing permits as they expire; USFS – no projected changes to grazing permits. State – renewing/modifying leases as they expire.
Animal unit Months	BLM-15,794 State- 943	Adjustments in AUMs may be proposed based on allotment- specific conditions, though no adjustments are proposed at this time.
Range Improvements	Fences-157 miles Pipelines-43 miles Developed Springs-67 Troughs-170 Stock ponds-35	Additional fencing, pipelines, and troughs may be constructed based on allotment-specific needs. At this time, 3 spring exclosures are planned in Horse Basin Pasture on the Mountain Springs Allotment.
Mining/ Infrastructural Developments		
Powerlines	64 miles	0 miles
Power Poles	806 poles	0 poles
Motorized Routes	BLM—506 miles USFS—19 miles	0 miles
Non-motorized Routes (Closed Motorized Routes)	11 mile	0 miles
Surface Mining	145 acres	0 acres
Sand and Gravel	124 acres	0 acres
Irrigation Diversions	7	0

*Data derived from Challis Road Layer dated 2011.

**Forest Service roads include open and seasonally closed natural and gravel surfaced roads and primitive trails. Data derived from Forest Service Roads layer dated 2008.

Livestock Grazing

Livestock grazing in the CIAA began in the 1870's when miners came into the area looking for gold in the nearby mountains, specifically Yankee Fork and Bayhorse. Livestock operators soon followed. Open range ranchers began moving into the valley in 1872 with cattle, horses, and sheep. It soon became apparent that winter forage was a limiting factor to ranching in the area. At that time, the Federal Government was encouraging settlement through the Homestead Act which forced open range ranchers to build fences and produce hay. As a result of the location of the CIAA relative to active mining and homesteading private lands in the CIAA were not developed until the early 1900's with the first patent of land being granted in 1912 and the majority of the private lands being patented by 1930.

In 1934, the Taylor Grazing Act was passed and the first grazing permits were issued. Livestock grazing was consistently reduced from 1948 to 1975 (USDI-BLM 1977). AUMs were further reduced through implementation of the 1977 Challis Grazing EIS.

There are currently 15 livestock grazing operators on 10 allotments (see Map 8) that are permitted to graze 15,794 AUMs on BLM-administered lands within the CIAA. In support of these operations, 43 miles of pipeline, 157 miles of fence, 170 troughs, and 35 stock ponds have been constructed.

Each of the allotments found in the CIAA have similar histories and have been continuously grazed since the 1870's. An example of this history is found in the Warm Springs Allotment. Warm Springs Allotment has been grazed since the inception of the US Grazing Service in 1936. The first permit allowed 9,800 sheep, 175 cattle and 20 horses. In 1957, a range adjudication reduced livestock grazing privileges by 20%. In 1960 a partial conversion was made from sheep to cattle at a ratio of 5 sheep to 1 cow. In 1963, following a range survey, grazing privileges were established at 1265 cattle for 7453 AUMs (Harbour 1975).

A number of vegetation manipulation projects have occurred within the CIAA in the past. These have occurred as either seedings, brush removals, prescribed fire and broadleaf spray directed at removing or reducing sagebrush canopy. These treatments occurred as follows: Warm Springs Allotment at 10,695 acres, Mountain Springs Allotment at 8,062 acres, Split Hoof Allotment at 980 acres and Bradbury Flat Allotment at 300 acres for a total treated acres of 20,037 acres.

Past livestock grazing has influenced the composition of vegetation due to dietary preference and selectivity of forage by livestock. Within the CIAA, 91% of the lands are available for livestock grazing managed by State and Federal agencies. Additional grazing occurs on private lands within the CIAA, but is not quantifiable. Livestock grazing impacts plants by removing the leaf area available for photosynthesis, removing of growing points, and reducing the ability of the plant to maintain a favorable shoot to root balance. This ultimately impacts the vegetation composition and the ability to meet long-term resource objectives for plant communities. Further, livestock grazing can mechanically impact vegetation through trampling. This is especially true in areas of livestock congregation (e.g. salt licks, water sources, and trails between foraging and watering areas) that potentially would be devoid of vegetation. Impacts to vegetation would also occur as a result of construction of range improvements. These impacts

include: removal of vegetation and/or crushing or trampling vegetation, as well as altering of streambanks and wetland areas. In response to patch grazing, spring and riparian corridor exclosures have been installed. However exclosures have only been shown to reduce cattle grazing along streams and upland springs not wild horse use.

Mining and Infrastructure Development

Infrastructural development in the CIAA has increased over time, although the majority remains undeveloped (see Table 22). Most of the development has occurred along the Herd, Road and Warm Spring Creek's bottom where private lands have been modified to accommodate farming and ranching activities; irrigation diversions occur along each of these creeks for the purpose of irrigating the private lands. The prominent land use within these private lands is irrigated pasture. The majority of open water which occurs in the CIAA is located on private lands in ponds used primarily for irrigation storage.

Table 22. Land Use/ Land Cover within the CIAA

Land Use/ Land Cover Type	Acres	Percent of CIAA
Open Water	30	0.01
Developed Open Space	524	0.21
Developed Low Intensity	992	0.40
Developed Medium Intensity	518	0.21
Barren Land (bedrock/sand/clay)	2218	0.89
Evergreen Forest	14293	5.73
Shrub/Scrub	173653	69.57
Grassland/Herbaceous	56071	22.46
Pasture/Hay	1150	0.46
Cultivated Crops	132	0.05
Woody Plants (hydric)	20	0.01
Herbaceous Plants (hydric)	13	0.01
*All data derived from USGS(2006) using a GIS		

A road network has been developed in the CIAA which accommodates a wide variety of vehicular traffic. To date, approximately 446 miles of primitive road (4WD) and ATV trails, less than 1 mile of naturally surfaced road, 30 miles of gravel-surfaced roads, and 30 miles of paved roads including US 93 crisscross the CIAA. As a result of a recent Travel Management Plan decision, 11 miles of BLM-administered roads/trails have been closed to motorized vehicles. The majority of these roads were developed to accommodate ranching and recreation.

Infrastructural development has resulted in the removal of acreage from existing riparian habitat. Within the CIAA, approximately 31% of perennial streams miles contain a road within their riparian corridor, resulting in the removal of as much as approximately 28 acres or ≈1% of the RHCA present in the CIAA. Road crossings in the form of culverts can result in contributions of sediment, but more importantly can influence juvenile and adult fish passage, often due to

undersized diameter and/ or slope which results in excessive velocity and perched outlets which create vertical impediments to fish passage. Road crossings of fish bearing streams are limited to tributary habitats; bridges associated with the Salmon and East Fork Salmon rivers do not limit fish passage. Due to the distribution of fish bearing stream and designated critical habitat, culverts which impede fish passage are limited to the Road Creek watershed. However, culvert replacements by the BLM have improved connectivity among habitats in upper Road Creek and its tributaries. Private lands and the East Fork Road near the mouth have culverts likely to impede fish passage under some conditions, and these are likely to foreseeably to persist.

There are irrigation diversions that likely influence stream flow seasonally in the lower reaches of Road Creek, which can limit fish habitat relative to volume and temperature. There are approximately 1.4 miles of Road Creek in which irrigation occurs within the RHCA for a total of 30 acres or ½ of 1% of the total RHCA available in the CIAA. This irrigation has a further effect on the downstream 0.4 miles of Road Creek in the CIAA by reducing the water available for hydric species. Due to the past construction of roads and their ongoing existence and maintenance there has been a cumulative removal of approximately 28 acres or ≈0.5% of RHCA. In lower Road Creek the RHCA along the ≈2 miles of Road Creek (≈3% of the RHCA relative to CIAA) have been affected by stream diversion, riparian conversion to pasture, and other private land development.

Power lines within the CIAA are located along the US 93 corridor through Warm Springs Valley, a power line bisects the CIAA near Spar Canyon connecting US 93 with the East Fork Salmon River Valley. A power line also runs up the lower portion of Road Creek delivering power to the private residences. In total there are 64 miles of power lines in the CIAA.

The largest mine with the CIAA is the Three Rivers Stone Quarry which has a total disturbed area of 124 acres. The Three River Stone Quarry has a National Pollution Discharge Elimination System permit from the U.S. Environmental Protection Agency authorizing the discharge of sediment. It was determined and concurred upon (January 2009) by USFWS and NMFS that the Three River Stone Quarry would result in only insignificant effects to habitat and T&E fish associated with the East Fork and mainstem Salmon rivers resultant from disturbance (e.g. blasting) or sediment conveyance from the quarry (USDI-BLM, 2008; USDI-BLM, 2009).

There are 21 additional acres associated with surface mining in the CIAA. These mine sites include a building stone prospect, zeolite prospect, precious gemstone prospect, and a gold prospect (there are no known occurrences of gold in the CIAA). There are 124 acres of common variety sand/gravel/rock sites within the CIAA. The majority of these sites are no longer active; there are 6 active sites for a total of 20 acres or 16% of the 124 acres of disturbance within the CIAA. There no active oil and or gas leases within the CIAA.

The great majority of the infrastructure and mines in the CIAA has been in place for decades. Relatively recent changes include the expansion of the Three Rivers Stone Quarry near the confluence of the East Fork into the main stem Salmon River. These alterations of the lands within the CIAA are generally widespread geographically and have not resulted in a noticeable progression toward a more urban orientation.

Reasonably Foreseeable Actions

Reasonably foreseeable future actions include continuation of past and present actions as described above. The level and character of livestock grazing and infrastructure are anticipated to remain consistent into the foreseeable future. Within the next 10 years the 15 livestock grazing permits are projected for renewal. Each of the livestock permittees has applied for their permits to be renewed. The permits would be renewed with similar Terms and Conditions or may be modified to ensure compliance with Fundamentals of Rangeland Health.

Future range improvement projects in the CIAA include 3 spring exclosures in the Mountain Springs Allotment in the Horse Basin Pasture (USDI –BLM 1999f). These spring exclosures would address a number of resource management issues including heavy use by wild horses and livestock. There are no mining and/or infrastructure developments in the reasonably foreseeable future in the CIAA.

4.1.1 Cumulative Impacts Associated with Past, Present and Reasonably Foreseeable Future Actions

Each of the past, present, and reasonably foreseeable future actions contribute a specific incremental environmental effect that can be described or accounted for with the same indicators as used in the alternative analysis presented earlier in the document. The proper indicator depends upon the analysis method used and the resource affected by the action. Indicators might be measured by the acres of soil disturbed, acres of big game habitat affected, miles of stream affected, percentage change in ground cover, number of springs developed, or whichever indicator of effect is best used to describe and account for the accumulated effect to the resource of concern. The accumulated effect of past, present, and reasonably foreseeable future actions on a given resource provides a baseline from which to evaluate the contribution of the alternatives to the collective impact on that resource. The purpose of this section of the document is to provide that baseline. The effects of the various alternatives on the baseline are presented in the subsequent section.

4.1.1.1 Wild Horses

The indicator for wild horses is horse health and safety. Under Alternative 1-4 wild horses would be maintained within AML, this in addition to the livestock grazing AUMs would continue to be within the carrying capacity and provide a thriving natural ecological balance. Alternative water sources (i.e. troughs, water holes) provide water for wild horses as well as for domestic livestock. Mining, sand and gravel operations, and the related actions have displaced wild horses from 269 acres within the CIAA. The 525 miles of road within the CIAA allow for motorized vehicle travel which may affect wild horse distribution and behavior. No additional roads would be created for the horse gather. Power lines /poles do not affect wild horse health and safety.

Under Alternative 5 wild horse numbers would exceed the AML. This in addition to the permitted livestock grazing AUMs would be above the carrying capacity for the public lands. Deterioration of uplands and riparian areas through an overpopulation of wild horses would not

improve habitat for future generations of wild horses or wildlife; cumulatively resulting in reduced AML or elimination of wild horses within this HMA.

No other past, present or reasonably foreseeable actions would offset the damage to the range caused by an ever increasing population of wild horses.

4.1.1.2 Vegetation Type, Communities, and Rangeland Resources

The indicator for vegetation is acres of concentrated disturbance. Areas associated with this are 170 troughs, 35 water holes, 157 miles of fence and 43 miles of pipelines within the CIAA. Assuming a disturbance diameter of 0.7 acres per water source (e.g., trough and stock ponds), an 8-foot disturbance width for fences, and an 18-inch disturbance width for pipelines, a total of approximately 304 acres or about 0.1% of surface vegetation within the CIAA has been altered from their natural state by livestock grazing and associated activities.

The duration and intensity of the effects of these disturbances are not equivalent. The 144 acres of disturbance associated with water sources tends to be relatively intense and long-term, while the 152 acres associated with trailing along fences is more likely to be locally intense, but discontinuous. This disturbance includes removal of vegetation along the fence, trampling of vegetation from livestock trailing along the fence, and from T-posts being pounded into the ground. The 8 acres of disturbance associated with pipeline installation occurred as single events with disturbances being relatively short-term (i.e., 2 to 3 years).

Mining, sand and gravel operation, and associated activities have resulted in 269 acres of concentrated disturbance of vegetative communities. There are 525 miles of road in the CIAA. Assuming an average road width of 20 feet there are approximately 1,300 acres of vegetation disturbance. The disturbance related to power lines/poles is related to the roads as described above and the individual poles. Disturbance of the individual poles would be negligible. Cumulatively, this has resulted in a total vegetative disturbance of 1,873 acres.

Under Alternatives 1-4 approximately 10 acres of new concentrated disturbance would occur to vegetative communities. Cumulatively this would result in a 0.5% increase in the number of disturbed acres within the CIAA.

Under Alternative 5 there would be no new concentrated disturbance associated with gather activities. However, no other past, present or reasonably foreseeable actions would offset the effects caused by an increasing population of wild horses. Complete removal of permitted livestock would not compensate for unregulated population growth within the CHMA. The population would eventually reach a level in which forage is inadequate to meet demand.

4.1.1.3 Livestock Management

The indicator for livestock grazing is number of permitted AUMs. Mining/infrastructure development has not affected permitted AUMs. Alternatives 1-4 would not affect permitted AUMs because the AML would be maintained providing a thriving natural ecological balance.

Under Alternative 5 livestock management would need to be modified such that permitted AUMs may be reduced or cancelled, because forage availability for livestock would be reduced as a result of increased wild horse populations.

4.1.1.4 Invasive/Non-native Species

The indicator for invasive/non-native species is acres of disturbance because activities that remove native vegetation and expose bare soil are likely to create niches where there is a potential for weed invasion. Generally, invasive species have been introduced to the CIAA as "hitchhikers" on vehicles or animals, as evidenced by the pattern of infestations. The acres of disturbance associated with these type of activities are disclosed under section 4.1.1.2 Vegetation Type, Communities, and Rangeland Resources.

There are 86 noxious weed locations mapped across ownerships in the CIAA for an approximate total of 75 acres (USDI-BLM 2009c). This total comprises approximately .03% of the total acreage within the CIAA. Cheatgrass infestations have not yet been mapped on BLM lands within the CIAA. General field observations indicate that infestations are occurring to some degree along roadways and on drier southwest facing aspects.

Alternatives 1-4 would result in a direct effect of approximately 10 or less acres of disturbance for noxious weeds to invade. Cumulatively this would result in a 0.5% increase in the number of disturbed acres for invasive species to establish.

Under Alternative 5 there would be no new concentrated disturbance associated with gather activities. Due to increased horse populations it is anticipated that invasive/non-native species occurrences would increase due to reduced vegetation and increased ground disturbance. This would result in an increased effort to manage invasive/non-native species.

4.1.1.5 Wetlands/Riparian Zones

The indicator for wetlands/riparian areas is acres of riparian affected. Livestock grazing has locally affected streams and upland springs. In response to these localized effects, grazing exclosures have been constructed. There are three proposed upland spring exclosures at sites where wild horse and livestock use have affected the springs. Mining/Infrastructural development has resulted in the removal of acreage from existing riparian habitat. Within the CIAA, approximately 31% of perennial streams miles contain a road within their riparian corridor, resulting in the removal of as much as approximately 28 acres or approximately ½ of 1% of the RHCA present in the CIAA. Installation of power poles within riparian corridors has removed approximately 0.004 acres or less than 1/10th of 1% of riparian areas present in the CIAA (Table 23).

Irrigation diversions dewater Road Creek and reduce water available for maintenance of riparian areas. The importance of the presence of water to sustained healthy riparian corridors cannot be understated. There are approximately 1.4 miles of Road Creek in which irrigation occurs within the RHCA for a total of 30 acres or ½ of 1% of the total RHCA available in the CIAA. This irrigation has a further effect the downstream 0.4 miles of Road Creek in the CIAA by reducing

the water available for hydric species. The irrigation of 30 acres typically requires a diversion rate of 0.6 cubic feet per second, any diversion in excess of this amount would be returned to Road Creek as ground water flow.

Table 23. Cumulative Effects on Riparian Areas and Vegetation

Resource	Total within CIAA	Total within the CHMA
Acres of RHCA(300-ft buffer of Perennial Streams)	5,914	3,487
305(b) Streams miles	306	251
303(d) Streams miles	214	95
Perennial Stream Miles	91.8	54.5
Road Miles Within RHCA (300-ft buffer of Perennial Streams)	28.8	14.4
Miles of Perennial Stream Affected by Mining	0	0
Miles of Power lines within the RHCA (300-ft buffer of Perennial Streams)	0.8	0.7
Number of Power Poles within the RHCA (300-ft buffer of Perennial Streams)	18	12
Number of Developed Springs (based upon USFS and BLM Range Improvement GIS Data)	27	19

1. Data were compiled from various sources using and at various scales (e.g. watershed scale, allotment scale) GIS. The values given are best estimates derived using this GIS data.
2. These data were used for the majority of the percentage calculations given

Cumulatively, past and present actions have resulted in the removal of approximately 28 acres or ≈0.5% of RHCA due to the construction of roads; approximately 145 acres (the RHCA along the 2 miles of Road Creek) or ≈3% of the RHCA have been impaired or affected as a result of stream dewatering and private land development; all of the acres of RHCA have been potentially affected by livestock and/or wild horses. All sites for which monitoring data is available are in late seral status or at potential natural community and have shown a static to improved trend from 1999-2012 (Table 14).

Under Alternatives 1- 4 no new acres of disturbance would occur within RHCAs therefore no cumulative effects are anticipated as a result of gather activities. Under Alternative 5, it is anticipated that use of riparian vegetation and alteration of wetland areas by wild horses would increase.

4.1.1.6 Water Quality

The indicator for water quality is macroinvertebrate assemblages. Aquatic macroinvertebrates can be used to assess water quality and the influence of organic pollutants. The assemblage of macroinvertebrate taxa are relatively sedentary and can be quantitatively sampled; some of the metrics used to describe the macroinvertebrate assemblage and contributions of different taxa include the number of pollutant intolerant species and number of clinger taxa (which can decrease as a result of sedimentation/siltation). Quantitative aquatic macroinvertebrate sampling conducted by the BLM between 1994 and 2008 indicates a static to upward trend in water quality for perennial streams across the CIAA (See Appendix H). These data, combined with relatively high levels of bank stability and predominately late-seral riparian vegetation (see Table 14), suggest that ongoing grazing actions managed with an array of passive and active methods and periodic horse gather operations to maintain AML have allowed for maintenance and/or recovery of elements of stream habitat important to water quality for fish bearing streams. Furthermore, macroinvertebrate data collected by IDEQ for streams across the CIAA indicate that macroinvertebrate communities are appropriate for the bioregions in which they were collected (See Appendix H). Cumulatively, at the CIAA scale, water quality has been affected by increased sedimentation and siltation due to grazing, horse use and road developments. Mines, sand and gravel operations, and power lines/poles within the CIAA do not occur proximal to RHCAs. Livestock and wild horse use have also resulted in fecal loadings to waters within the CIAA.

Under Alternatives 1-4, it is anticipated that macroinvertebrate assemblages would continue to show a static to upward trend in water quality. Under Alternative 5, macroinvertebrate assemblages (e.g. relative abundance of clinger and pollutant taxa) could reflect increased wild horse use in riparian areas.

4.1.1.7 Threatened / Endangered and Sensitive Fish; Fisheries

The indicator for Threatened/Endangered and Sensitive Fish; Fisheries is miles of ESA designated critical habitat for fish, which includes all fish bearing streams (see Table 24) affected. Under Alternatives 1- 4 no new acres of disturbance would occur within RHCAs therefore no cumulative effects are anticipated for the miles of ESA designated critical habitat as

a result of gather activities. Under Alternative 5, it is anticipated that the pattern of wild horse use of riparian vegetation and alteration of streambanks would expand.

Table 24. Threatened/Endangered and Sensitive Fish; Fisheries Resources and Cumulative Effects		
Resource	Total within CIAA	Total within the CHMA
Acres on State and Federal Lands Subject to Grazing	227,270	149,343
Perennial Stream Miles	91.8	54.5
Approximate Fish Bearing Stream Miles	43.5	32.5
Miles of Designated Critical Habitat for Chinook Salmon	44.8	37.3
Miles of Designated Critical Habitat for Steelhead	3.3	1.6
Miles of Designated Critical Habitat for Bull Trout	1.8	1.5
Road Miles Within RHCA (300-ft buffer of Perennial Streams)	28.8	14.4
Miles of Perennial Streams where grazing is authorized	89.2	52.3
Acres of Grazing Exclosures	138	138
Miles of Perennial Streams within Exclosures	1.5	1.5

4.1.1.8 Wilderness

For the purposes of analyzing cumulative impacts, the CIAA for wilderness values includes the entirety of the Jerry Peak and Corral-Horse Basin WSAs (92,650 acres, combined). Due to the nature of WSAs some of the actions which have cumulatively affected the rest of the CIAA have not, and would not, occur within the boundaries of these special designations (agricultural development, road construction, and land use conversions). Both WSAs were found during Intensive Wilderness Inventory in 1980 to have certain wilderness values (size, naturalness, outstanding opportunities for either solitude or primitive and unconfined recreation, and supplemental values).

There have been no past and present actions which have impacted the size of the either WSA. There has been some amount of primitive road development (motorized routes created by the passage of vehicles) since the time of inventory, however, these routes were inventoried and closed during the 2008 travel planning effort. There have been no road construction or maintenance efforts that have affected the boundaries, and subsequent size, of either WSA.

The Jerry Peak WSA contains 1.4 miles of buried pipeline, 17 miles of primitive routes, 27.3 miles of fence, and 7 troughs. Corral-Horse Basin WSA contains 2.4 miles of buried pipeline, 34 miles of primitive routes, 25.8 miles of fence, and 9 troughs. All of these developments affect the naturalness of the WSAs to some degree, though the pipelines effectively disappear after one or two growing seasons. The 51 miles of primitive routes are all single vehicle width and have no impacts associated with construction, resulting in an average disturbance width of 8' and 49 acres of disturbance across both WSAs. The 53 miles of fence result in 51 acres of disturbance (assuming a worst-case scenario of 8' of initial vegetative disturbance), and the 16 troughs impact 10.5 acres. Therefore, the cumulative physical impacts to naturalness associated with the existing developments are approximately 110 acres, or .1% of the combined acreage of the WSAs. There would be no new facilities associated with the proposed action or alternatives. There are eight potential capture sites which might be utilized 'within the boundaries' of the WSAs. Of these eight sites, one is located on private land, one on State land, and four are on Road Creek Road. Approximately one acre of vegetation could be trampled during gather operations at each of the 6 of the capture sites on or directly adjacent to the WSAs, resulting in an additional six acres of temporary physical disturbance (.006% of the WSA acreage).

Outstanding opportunities for solitude could be reduced during helicopter operations, though they would not cumulatively affect the long term availability of solitude (or primitive recreation) within the impact area. Finally, managing the wild horse herd for the appropriate management level would maintain the supplemental values identified during inventory at a healthy and sustainable level.

4.1.1.9 Recreational Use, Existing and Potential

In the CIAA, recreational use has been affected, and would continue to be affected, by certain elements of grazing management and mining/infrastructure development. The common denominators, when considering the cumulative impact of these broad activities to recreational

use, are the elements/indicators which have the potential to affect the naturalness (or scenic) quality of the landscape or the ability of visitors to freely traverse the landscape.

Past and present grazing related actions which have cumulatively combined to affect the natural across quality of the CIAA include the construction of 157 miles of fencing, 43 miles of pipeline, 170 water troughs, and 35 stockponds. The impact of pipelines is nearly non-existent because once the initial, short term disturbance recovers; their evidence on the landscape becomes virtually unnoticeable to the casual observer. The presence of 170 troughs within the CIAA equates to one trough for every 1,437 acres of publically accessible land within the CIAA. With an effective impact of approximately 0.7 acres/trough, the impact to the naturalness of the area becomes very limited (approximately 119 acres). Waterholes have a similar impact area of 0.7 acres/waterhole, resulting in approximately 25 acres of disturbance across the CIAA. The presence of fencing affects both the naturalness of the area, as well as the ability for a recreationist to move freely throughout the ERMA. With 244,349 acres of publicly accessible land within the CIAA (381 square miles), there currently exists approximately one mile of fence for every 2.5 square miles. At an average disturbance width for fence construction of 8 feet, this would directly affect approximately 152 acres. While additional fencing, troughs, and pipelines may be constructed in the future based on specific needs, the only additional grazing developments in the foreseeable future are the 3 potential spring exclosures in Mountain Springs Allotment. By nature, small exclosure fences result in minimal impacts to freedom of movement for recreationists and impact the naturalness of an area at a localized scale.

Motorized routes (trails, roads, and primitive roads) also affect both the naturalness of the area and the ability to traverse the landscape. Dependent on the activity, and more so on the perception of the user, motorized routes can add or detract from the recreational experience. However, regardless of the experience, 525 miles of designated motorized routes within the CIAA directly affects the naturalness of the area by the disturbance of approximately 1,536 acres of vegetation (assuming an average width of disturbance of 25 feet), or 0.6% of the CIAA. The BLM has recently completed a travel management plan which affects the CIAA and there are no known plans for designating new motorized routes in the foreseeable future. There are 11 miles of existing routes on the BLM within the CIAA which have been closed to motorized use and would be expected to return to a natural condition as use diminishes over time.

The remaining key elements within the CIAA that affect the naturalness of the area are land use conversions (irrigated private lands and mineral extraction developments) and infrastructure related to rural development (such as powerlines and homes). These actions tend to be concentrated in the valley bottom, within or close to, private lands and county roads. In total, these activities have reduced the quality of naturalness on approximately 2,282 acres or less than 1% (this is the acreage for Developed Open Space, Developed Low Intensity, Developed Mod Intensity, and the 248 acres of surface mining identified in the CIAA description) of the assessment area by removing natural vegetation, disturbing soils, and facilities construction. There are no known plans for additional land use conversions or infrastructure development in the foreseeable future.

The impacts associated with the proposed action and alternatives considered in this analysis would not result in any measurable cumulative impacts to recreational experiences or

opportunities. There would be no addition or subtractions to the road and fencing systems which impact recreational mobility, nor would there be any impacts to the naturalness of the area beyond short term impacts to vegetation at discrete capture sites (less than 20 combined acres across the CIAA, or .008%).

4.1.1.10 Soils

Soils within the CIAA have been impacted by disturbances. The majority of grazing impacts (livestock, and wild horse) occur around existing water sources such as springs, troughs, stock ponds, areas providing cover or shade and along fence lines where livestock and horses tend to trail. The soils within and closely surrounding these areas receive heightened use and may exhibit signs of soil compaction, erosion, and reduced productivity. These areas of decreased vegetation and litter cover are generally more susceptible to soil erosion, increased runoff, and infestation by invasive, non-native plant species. Pipelines, not typically areas of intensive use, also disturb vegetation and soils as a consequence of their installation for the short term, but recover within 2 to 3 years. The indicator for soils is acres of concentrated surface disturbance. The acres of concentrated disturbance are described under 4.1.1.2 Vegetation Type, Communities, and Rangeland Resources.

Under Alternatives 1-4 approximately 10 acres of new concentrated disturbance would occur to soils. Cumulatively this would result in a 0.5% increase in the number of disturbed acres within the CIAA.

Under Alternative 5, there would be no new concentrated disturbance associated with gather activities. However, no other past, present or reasonably foreseeable actions would offset the effects caused by an increasing population of wild horses. Complete removal of permitted livestock would not compensate for unregulated population growth within the CHMA. The population would eventually reach a level in which forage is inadequate to meet demand. The decrease in vegetation cover would result in increased erosion.

4.1.1.11 Threatened/Endangered/Sensitive Animals/Migratory Birds/Wildlife

Cumulative effects on wildlife are those impacts that alter or remove a measurable portion of natural processes that individual species have evolved to need during some portion of their life. BLM recognizes that individuals or portions of populations could move in and out of the representative CIAA. The CIAA used here is delineated to encompass the majority of the population of each specific species that use the habitat influenced by the actions proposed in this document in conjunction with the cumulative impacts occurring to the habitat within the CIAA boundary. The CIAA also fits within the scope of BLM CFO's purview and capabilities of accurate analysis for the time, intensity, and scope of cumulative impacts. The CIAA is also delineated as to accurately represent cumulative impacts to each species and not be overly large as to dilute potential impacts. Analysis under this section of cumulative effects would focus on habitat health within the CIAA as described in this document and how the health of the CIAA impacts different species that uses it.

Greater Sage-Grouse

The indicators for impacts to Sage-grouse are the removal of habitat and direct disturbance or removal of individuals by the above described activities. Cumulative effects analysis in this section would focus on sagebrush steppe health of the CIAA. However, sage-grouse population trend is indicative of the stochasticity (unpredictable spatiotemporal fluctuations in the environment) of the sagebrush ecosystem and population trend would be discussed in an effort to determine sagebrush steppe health. Interim Management (IM-2012-043) designated 27% (68,292 acres) of the CIAA as Preliminary General Habitat (PGH) and 69% (173,865 acres) as Preliminary Priority Habitat (PPH). PPH covers the majority of the CIAA with PGH only being present around the periphery of unsuitable sage-grouse habitat. Sage-grouse movements are not well understood, but site fidelity has been documented by sage-grouse. Males have been documented showing site fidelity to lekking sites and females showing fidelity for nesting areas (Connelly 2004). The gather is scheduled to take place outside of the lekking and nesting period. The scheduled gather period takes place during the sage-grouse summer period (7/1 – 11/15). Mapped CSGLWG summer seasonal habitat occurs on the southern half of the CIAA and is generally associated with higher elevations of the CIAA. According to Garton (2011) the Big Lost sage-grouse subpopulation extents into the south east half of the CIAA.

Summer seasonal habitat for the CHMA within the alternatives equates to 64% (37,822 acres) of that mapped by CSGLWG (59,180 acres) within the CIAA.

Greater sage-grouse within the CIAA have been impacted in varying degrees by all of the past, present, and reasonable foreseeable future actions. Impacts from ungulate grazing occur in the form of altering the sagebrush and herbaceous cover needed for sage-grouse habitat, and nest trampling. Grazing of wild ungulates occurred throughout the region at various levels prior to European settlements. Livestock grazing prior to the passage of the Taylor Grazing Act and pre-European settlement native ungulate grazing intensities are not known. After passage of the Taylor Grazing Act in 1934 livestock have been present throughout the CIAA in different forms, seasons, and rates. Impacts associated with livestock developments include fences, troughs, waterholes, and pipelines. The total acreage impacted by these developments is 304 acres or approximately 0.1% of the CIAA. These developments have different levels of impacts on sage-grouse. Impacts associated with waterholes and pipelines are generally limited to construction. Troughs pose a potential for entrapment if bird ramps are not maintained and fences have the potential for impacts to low flying individuals. There are 170 trough locations within the CIAA. Using the 0.7 acres of disturbance of sage-grouse habitat per water trough equates to a loss of approximately 119 acres or 0.04% of the CIAA. There are 157 miles of fence on State and Federal lands within the CIAA. The density of fencing within the CIAA is 0.4 miles of fence per square mile. This density of fencing is below the 1.6 miles of fence per square mile that poses a higher risk for sage-grouse (USDI-BLM 2011).

Infrastructure development can have different forms and different direct and indirect impacts on sage-grouse that occur within the CIAA. There is 64 miles of powerlines within the CIAA. Power poles that have the potential to be used by raptors as a perch but do not have perch deterrents installed and exist within the sage grouse habitat would continue to provide raptors an opportunity to be used as such. There are 506 miles of roads within the CIAA. Existing routes

have the potential to aid the spread of invasive weeds. Possible impacts from roads within sage-grouse habitat include the spread of invasive weeds, habitat fragmentation, and direct disturbance or mortality depending on the amount occurring and the frequency used. There is 145 acres of surface mining occurring in the CIAA. Open pit mining activities remove habitat from use by sage-grouse for typically long periods of time.

Pygmy Rabbit

The indicators for impacts to pygmy rabbits are the removal of habitat and direct disturbance or removal of individuals by the above described activities. Power poles can provide perches for raptors. There are 64 miles of powerlines within the CIAA. Power poles that are present around pygmy rabbit activity and do not have perch deterrents installed would continue to provide a perching opportunity for raptors. Roads can promote invasive weeds and fragment habitat. Mining activities can remove habitat for pygmy rabbits during active mining.

Migratory Birds

The indicators for impacts to migratory birds are the removal of habitat and direct disturbance or removal of individuals by the above described activities. Migratory birds have the potential to exist throughout the CIAA on all habitat types. The majority of ungulate use takes place in shrub steppe habitat. Ungulate grazing has the potential to be present throughout the CIAA during the entire breeding/nesting season. Habitat conversions are not detrimental on a species level if other habitat is available. Open pit mining activities of all scales typically remove vegetation during normal operations. Vegetation removal and disturbances during breeding/nesting season have the potential to cause breeding/nesting failure. The extent to which this has happened in the CIAA is not known. Infrastructure development also has the ability to impact birds positively and negatively. Vehicle collisions increase as roads develop and speeds increase. Powerlines can provide perches for birds and act as a surrogate to natural structures. Some powerline designs can also cause electrocutions when birds come in contact with them.

Gray Wolf

The indicators for gray wolves are direct disturbance or removal and the altering of prey abundance and composition. Factors influencing how many wolves might be removed because of depredation are numerous. Wolves that have been removed because of past depredation have not inhibited wolf population growth in Idaho since their reintroduction in 1995. Wolves are highly mobile and use habitat on a landscape scale. The remaining elements as described in the past and present actions are at a scale that has not shown impacts to wolves as a species. Wolves have continued to expand their range and population since their reintroduction.

Other Big Game

The indicators for big game are direct competition for resources, removal of vegetation, and direct disturbance. Horse and livestock grazing takes place throughout the majority of the CIAA. Infrastructure development can remove big game habitat, cause mortalities, and influence behavior. There are 506 miles of designated routes within the CIAA. There is 145 acres of

surface mining in the CIAA. Infrastructure development can remove or fragment available big game habitat. Vegetation treatments are generally favorable to big game. There have been 20,037 acres of vegetation treatments in the past in the CIAA. Vegetation treatments act as a controlled surrogate to wildfire and reset successional changes to provide a mosaic of vegetation availability that can benefit big game.

Cumulative Impacts Common to All Species

Under Alternatives 1-4 approximately 10 acres of new concentrated disturbances would occur to vegetative communities. Cumulatively this would result in a 0.5% increase in the number of disturbed acres. The proposed actions within this alternative are isolated and limited to this one action. The proposed gather actions (herding, trapping, and transportation) would have a negative impact to individual wildlife species present during activities. The actions would be limited both spatially and temporally. A reduction in the horse herd would lesson forage removal/consumption and the potential for disturbances by horses. These actions, when added to other past, present, and reasonably foreseeable actions, would not lead to the listing of any of the species described in this document and present within the CIAA.

Under Alternative 5 horse herd number would increase and lead to greater consumption of forage and a greater potential for disturbances to wildlife. The proposed actions in this alternative would lead to the horse herd numbers increasing. There are no gather activities associated with this alternative. Horse herd number would continue to increase. The AML would continue to be exceeded and forage not allocated to horses would be removed. This would lead to an increase in completion for forage and potential for disturbance of wildlife, as well as, a decrease in cover for certain wildlife. However, these actions, when added to other past, present, and reasonably foreseeable actions, would not lead to the listing of any of the species described in this document and present within the CIAA within the proposed time period in this alternative of ten years.

4.1.1.12 Tribal Treaty Rights

Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. Within the Challis Horse Management Area (CHMA), there are 154,150 acres of BLM lands, 9,454 acres of State of Idaho lands, and 1,116 acres of privately owned lands. Access to treaty reserved resources within the Shoshone-Bannock Tribes' aboriginal territory may no longer be possible on privately owned lands within the CHMA because of land status and/or access restrictions.

The federal government has a federal trust responsibility to manage public lands to provide for the continued exercise of tribal treaty rights, consistent with management policies, on all unoccupied lands within their jurisdiction. The proposed action and alternatives analyze potential management actions designed to address appropriate and effective wild horse management on lands within the CHMA. Provisions are also made to protect the safety and health of the horses, BLM employees and contractors during actual gather activities, and may include short-term area closures within the CHMA.

Any short-term temporary areal closures deemed necessary would not alter federal land status, but would necessarily limit access to and utilization of treaty-reserved resources on unoccupied

federal lands during actual wild horse gather activities. Impacts to access of specific areas within the CHMA would last between 4-8 days over an approximate two-week period in October.

Detailed discussion of potential cumulative impacts to resources of special interest to the Shoshone-Bannock Tribes such as water quality, fisheries, vegetation, ad wildlife are analyzed and discussed in detail within those specific sections (e.g., Fisheries, Vegetation) located elsewhere within this document.

4.1.1.13 Human Health and Safety

Members of the public can inadvertently wander into areas that put them in the path of wild horses that are being herded or handled during the gather operations, creating the potential for injury to wild horses and to the BLM employees and contractors conducting the gather and/or handling the horses as well as to the public themselves. Because these horses are wild animals, there is always the potential for injury when humans get too close or inadvertently get in the way of gather activities.

The helicopter work is done at various heights above the ground, from as little as 10-15 feet (when herding the animals the last short distance to the capture site) to several hundred feet (when doing a reconnaissance of the area). While helicopters are highly maneuverable and the pilots are very skilled in their operation, unknown and unexpected obstacles in their path can impact their ability to react in time to avoid members of the public in their path. These same unknown and unexpected obstacles can impact wild horses being herded by the helicopter in that they may not be able to react and can be potentially harmed or caused to flee which can lead to injury and additional stress. When the helicopter is working close to the ground, the rotor wash of the helicopter is a safety concern by potentially causing loose vegetation, dirt, and other objects to fly through the air which can strike or land on anyone in close proximity as well as cause decreased vision. Though rare, helicopter crashes and hard landings can and have occurred (approximately 10) over the last 30+ years while conducting wild horse and burro gathers which necessitates the need to follow gather operations and visitor protocols at every wild horse and burro gather to assure safety of all people and animals involved. Flying debris caused by a helicopter incident poses a safety concern to BLM and contractor staff, visitors, and the wild horses.

4.1.1.14 Socioeconomics

The CIAA is located in Custer County, a rural area with an estimated population of 4,368 (U.S. Department of Commerce 2010). Over the last ten years, the county's population has remained more or less static, increasing by 0.6%. The primary population centers within the county are Challis (pop. 1,081), Mackay (pop.517), and Stanley (pop. 63). Population density within the county is low at an estimated 0.88 persons per square mile, in part because 97% of the county is in federal or state ownership.

Median household income as of 2010 was $41,773.00, slightly below the state median of $44, 640.00.

Traditionally, the largest employment sectors in the county have been mining, government and agriculture, though employment patterns have shifted markedly through time. According to the U.S. Department of Commerce (2011), employment in the mining sector shrunk from approximately 38% of total employment in 1998 to 10% in 2003. Since 2003, the mining sector has seen more or less steady growth, reaching approximately 37% of total employment by 2009.

Employment in government fluctuated to a lesser degree. In 1998, the percentage of total jobs in federal, county, or local government was approximately 16%; it grew markedly to 24% by 1993 and then shrank to its 2009 level of 17.4%.

In contrast to employment in the mining and government sectors, employment in the services sector has seen steady growth within the county and as of 2009, represented 65.2 % of total employment (U.S. Department Commerce 2011). Within the services sector, relatively low paying jobs in accommodation, food service and retail trade now rival higher paying jobs in mining as the dominant source of income in the county.

The trend in agricultural employment, on the other hand, has been one of slow, but steady decline. Since 1970, farm employment shrank by approximately 21% and, as of 2009, comprised 10.5 % of total employment in the county (U.S Department of Commerce 2011, 2001).

One reason for the slow and steady decline in the agricultural sector is suggested by farm operator earnings. As indicated in Table 25, net average cash income from farms has been well below the median income for the county as a whole (when adjusted for inflation). A substantial number of farms have operated with a net loss. It is clear that one means to keep the farm operating under these circumstances is to supplement their income by working off the farm. As indicated in Table 25, more than half of the operators in the county worked off the farm for at least some portion of the year during the 1992-2007 period, many for more than 200 days a year.

Table 25. Farm operators net average cash income and days worked off the farm, Custer County, 1992-2007.

	Net average cash income from farms (dollars adjusted for inflation, 2011)	Operators with net losses (percentage of total)	Operators working off farm for any number of days (percentage of total)	Operators working off farm more than 200 days in a year
1992	13,819	169 (63.3)	144 (53.9)	84 (31.5)
1997	13,292	158 (59.0)	158 (59.0)	95 (35.4)
2002	(4,407)	212 (74.4)	164 (57.5)	111(38.9)
2007	27,676	74 (28.4)	182 (69.7)	76 (29.1)

United States Department of Agriculture (1992b, 1997a, 1997b, 2002, 2007c)

Several researchers have noted that profit is not the primary motivating factor in the choice to remain on the farm. In their study of ranching in Colorado, Bartlett et al. (1989) concluded that rate of return was of little or no importance in the rancher's decision to stay in the cattle business with most respondents citing the ranching way of life as their principal motivating factor. Similarly, Rowe et al. (2001) indicate that tradition, place attachment, and family were the primary motivating factors to stay in agriculture. Similar motivations have also been discussed by Liffman et al. (2000) and Bartlett et al. (2002). When ranchers do choose to sell, typical motivations cited are a lack of heirs, impending retirement, and detrimental public policy with lack of profitability being one of the least cited reasons. These factors may explain the rather slow pace of decline in the agricultural sector within the county.

The steep level of growth in the retail trade and accommodation/food service sectors and the gradual decline of the more traditional agricultural sector are accompanied by potential social consequences. In their study of Owyhee County, Idaho, Harp and Rimby (2004) found that communities characterized by ranching displayed higher levels of cohesion, integration, and attachment than those that did not, and argue that declines in ranching would result in similar reductions in these societal characteristics. Winkler et al. (2007) describe a similar decline in extractive-oriented economic structures in communities throughout the Intermountain West and a new orientation towards natural and cultural amenities. The result has been an in-migration of "outsiders", the presence of seasonal populations, increasing tourism and higher housing values; a phenomenon characteristic of the "New West."

While declines in societal cohesion and integration and the transformations characteristic of the "New West" phenomenon are not readily apparent in the communities within Custer County, these types of changes may become more apparent in the future given current trends in economic indicators.

5.0 Monitoring and Mitigation Measures

The BLM Contracting Officer's Representative (COR) and Project Inspectors (PIs) assigned to the gather would be responsible for ensuring contract personnel abide by the contract specifications and the SOPs (Appendix B). Ongoing monitoring of forage condition and utilization, water availability, aerial population surveys, rangeland resources health, and animal health would continue.

Fertility control monitoring would be conducted in accordance with the SOPs (Appendix B). Monitoring the herd's social behavior would be incorporated into routine monitoring. The objective of this additional monitoring would be to determine if additional stallions form bachelor bands or are more aggressive with breeding bands for the forage and water present.

If genetic monitoring indicates a loss of genetic diversity, then mares would be introduced into the CHMA from another HMA with similar characteristics.

6.0 List of Preparers

The following list identifies the interdisciplinary team member's area of responsibility:
Kevin Lloyd, Wild Horse and Burro Specialist/Rangeland Management Specialist
Peggy Redick, Supervisory Resource Management Specialist

Kyle Jackson, Rangeland Management Specialist
Bart Zwetzig, Wildlife Biologist
Ryan Beatty, Fisheries Biologist
Carol Hearne, Archeologist/Supervisory Resource Management Specialist
Nate Arave, Hydrologist
Leigh Redick, Invasive Species
Jeff Christenson, Outdoor Recreation Planner

7.0 Government to Government Consultation

Government to government consultation with the Shoshone-Bannock Tribes was initiated. The Tribal Business Committee was notified concerning the gather through the scoping letter BLM staff and Tribal technical staff meetings occurred on 4/26/2012. To date, no concerns about short- or long-term impacts to tribal treaty rights or access have been expressed by the Tribes.

7.1 Public Consultation and Coordination

A scoping letter dated February 3, 2012 was mailed to 41 individuals, agencies, and organizations on the interested public list for the Challis Herd Management Area, Wilderness List, and the associated Allotment Lists. In addition to the scoping letter an open house was held at the Challis Field Office on February 24, 2012 to answer questions and receive comments. Six comments were received at the Open House. Additionally, over 4,000 comments were received from interested publics during the scoping process. All scoping comments were carefully considered and addressed in the Environmental Assessment (EA).

A statewide Helicopter Hearing for the use of motorized vehicles in the management of wild horses was held in Kimberly, Idaho on March 7, 2012. Six individuals attended and four commented on the use of helicopters. All of the individuals that commented supported the use of motorized vehicles in particular helicopters in the management of wild horses. Time was available following the meeting to comment on the proposed gathers in Challis.

News releases throughout the state invited interested publics to attend the meetings.

9.0 Appendices

Appendix A: Gather Plan

The purpose of the gather plan is to outline the methods and procedures for conducting a gather to remove excess wild horses from public lands administered by the CFO. Implementation of the Proposed Action would require the capture of 274 and removal of approximately 137 wild horses to achieve a post-gather population of 185 wild horses. An adoption will be held at the Challis Wild Horse Facility following vaccinations, freezmarking, deworming, gelding and blood being drawn for Coggin's test.

A. Gather Area

The Proposed Gather Area includes the CHMA and areas outside of the CHMA boundary east of Highway 93. The CHMA is 168,468 total acres including federal, state and private lands. Refer to Map 8, which displays the CHMA, grazing allotments and the gather area.

B. Administration of the Contract /Gather Operations

The National Wild Horse and Burro Gather Contract would be used to conduct the wild horse gather tentatively scheduled for October 2012. BLM personnel would be responsible for overseeing the contract for the capture, care, aging, and temporary holding of wild horses from the capture area. BLM WH&B Specialists would be present during all aspects of the gather activities.

Standard Operating Procedures (SOPs) described within this document (Appendix B) would be utilized for the capture and handling of wild horses and burros, and have been developed over time to ensure minimal impacts associated with gathering, handling, and transporting wild horses and burros and collecting herd data.

It is estimated that 3-5 capture sites and 1 set of central sorting/holding facility would be necessary to complete the gather. Ideally, capture sites would be established away from riparian vegetation and stream channels in areas of previous soil or vegetation disturbance (such as gravel pits and roads), to avoid impacts to aquatic habitat, unaltered vegetation, cultural resources and soils.

Branded and/or claimed horses would be transported to a temporary sorting/holding facility. Ownership would be determined under the estray laws of the State of Idaho by an Idaho Brand Inspector. Collection of gather fees and any appropriate trespass charges would be collected per BLM policy and regulation.

An APHIS DVM or other licensed DVM would be on-site for the duration of the gather to provide recommendations to WH&B Specialists for care and treatment of sick or injured wild horses as per the 1983 Consent Decree. Consultation with the DVM may take place prior to the euthanasia of wild horses in accordance with Washington Office Instruction Memorandum (IM 2009-041). Refer to Appendix B, Part E for more information about the euthanasia policy.

Precautions would be taken to ensure that young or weak horse foals are safely gathered and cared for appropriately. If a band has a small foal that can't keep the mare and foal are left and not gathered. If the pilot is unable to determine which mare the foal belongs to than the entire band may be left ungathered. In some instances the may be gathered by wranglers that are guided to the foals location by the pilot. Every effort is made to reunite mares and foals as soon as they arrive at the sorting facility. If a foal were determined to be an orphan, qualified adopters would be contacted immediately to provide proper care for the foal. Milk replacer formula and electrolytes would be available to care for orphan foals if necessary.

C. General Overview of Wild Horse and Horse Gather Methods

The contractor supplies and transports all equipment needed to conduct a gather to a central location where a sorting/holding facility is constructed, which consists of six or more pens constructed of sturdy panels 6 feet high, with a central alleyway and working/squeeze chute in the center. Corral panels are covered with snow fencing to keep animals calm and to create a visual barrier reducing disturbances and to reduce collisions, and water tanks are located within the pens. The central alley and pen arrangement allows the BLM staff and the contractor to sort recently captured animals, separating animals to ship to the adoption facilities, and mares and foals from stallions to prevent fighting and injury. The pen arrangement allows the contractor to off-load wild horses from stock trailers into the pens, and facilitates the loading of the horses to be transported to facilities onto large straight deck trucks.

At various locations throughout the CHMA, smaller sets of capture sites are constructed in order to gather horses in the proximal vicinity of where wild horse herds are located. The capture sites or capture sites consist of a series of pens made out of sturdy steel panels six feet tall, and wings made out of jute (a fibrous material) and "T" posts that funnel wild horses into the corrals as they are captured. Once captured, the horses are loaded into stock trailers and transported to the central sorting/holding facility. Horses typically remain less than 24 hours at the capture site before being transported to the sorting/holding facility. Horses may also spend up to an hour one stock trailers while other groups of horses are brought to the capture sites.

The contractor utilizes a helicopter and pilot to conduct gathers. Use of a helicopter is humane, safe and effective. Methods for use of helicopter are well established after over 30 years of BLM WH&B experience. Contract pilots are certified for the moving of animals under governmental contract. Experience and field observations have shown that wild horses settle down once gathered and are more concerned with intra-species dominance than the helicopter. The pilot locates groups of wild horses within the CHMA and guides them towards the capture corrals. In most cases, horses are allowed to travel at their own pace, and are not pushed. Distances average 4-7 miles over mixed terrain which may consist of rolling foothills or steeper terrain, drainages, ridges and valley bottoms. The horses often follow their own trails. The pilot, BLM staff (including the Contract Officer Representative and the Project Inspector) and APHIS DVMs monitor the condition of the horses to ensure their safety, checking for signs of exhaustion, injuries etc. The contractor and pilots are very skilled at designing and building capture corrals, and safely herding the horses to them. Generally, wild horses are very fit, and recover quickly from being captured. Distances that the horses travel are modified to account for summer temperatures, snow depth, animals in weakened condition, young foals, or older/lame animals.

Under ideal conditions, some horses could be herded 10 miles at the discretion of the COR/WH&B Specialist.

Once near the capture site, the contractor holds a Prada horse (a tame trained horse) at the mouth of the wings. As the pilot pushes the wild horses closer, the Prada horse is released, which then runs into the capture corrals, leading all of the wild horses with him. Crewmembers rush in to secure gates once the horses are within the corrals. During summer gathers, the crew often separates foals from adults at the capture site so that they may be transported to the Sorting/holding facility separately and avoids being injured by adult horses. Foals may be loaded into a separate stock trailer where they can have shade, water, and electrolyte if necessary. Once unloaded at the sorting/holding facility, foals may be rejoined with the mothers if not old enough to wean, and monitored to ensure that all of the foals "join-up" or reunited with their dams. Often paint marks are applied to the foals and mothers to assist the contractor and BLM staff in identifying pairs.

Occasionally (and more frequently for difficult to gather areas) helicopter-assisted roping is implemented, in which the pilot moves a small group of horses to the gather area, and the crewmembers rope the animals from horseback. This method often prevents overstressing the horses from repeated attempts to move them into the capture corrals. The roped horses are then led to the corrals, to awaiting stock trailers, or immobilized on the ground (less than 30 minutes) until they can be loaded into stock trailers.

Once horses are loaded and transported to the sorting/holding facilities, they are sorted by the contractor‘s staff and BLM employees. The contractor looks at the horse‘s teeth to estimate age while held in the chute, and the BLM staff documents age, color, body condition and lactation status of the horse. Aging wild horses is a process of estimation due to the type of wear that can occur to the teeth of a wild horse on the range. Injuries are noted and treated if needed. Once sorted, the horses are given hay and unlimited water, if no health concerns exist. During this time, the BLM may consult with a DVM to treat sick or injured animals, or make recommendations for euthanasia.

When sufficient numbers of horses to be removed are available at the sorting/holding facility, they are loaded into the straight deck trailers that hold 35-45 wild horses depending upon their size semi-tractor trailer will transport horses to the Challis Preparation Facility on Upper Hot Springs Road in Challis, Idaho. This requires separating horses remaining in the CHMA from those to be removed. The trailers have three compartments so that mares, stallions and foals can be transported separately. Transportation time is estimated to be an hour from the sorting/holding facility to the Challis Preparation Facility. If additional room is required or for any other reason horses are not able to be shipped to the Challis Facility, they will be shipped the Boise Idaho Facility or the Rock Springs Wyoming Facility, both approximately 5-7 hours away.

During sorting, BLM staff identifies wild horses to be released back to the CHMA based on the National Selective removal guidance, fertility control and historic characteristics. Mares may be held until the end of the gather so that fertility control can be given to them to slow future population growth rates. When it is time for the release, the mares and stallions are each loaded into separate stock trailers and transported back inside the CHMA. The rear of the trailer is

opened up, and the horses are allowed to step off and travel back into the CHMA. Sometimes the horses are released directly from the sorting/holding facility located within the CHMA.

Before the wild horses are released back to CHMA, hair samples would be collected for genetic testing from 40 random individuals that are gathered from varying parts of the CHMA. Data collected during the gather in conjunction with previous genetic analysis reports will be used to monitor the genetic health of the CHMA.

D. Data Collection

The WH&B Specialist would be responsible for collecting population data on individual HMAs. The extent to which data is collected may vary among the field offices to meet specific needs pertaining to each HMA.

1) Hair Samples/Genetics Analysis

Hair samples would be collected for genetic testing from 40 random individuals that are gathered from varying parts of the CHMA and analyzed for genetic trend data (last collected in 2002) of wild horses (genetic diversity (heterozygosity), historical origins and unique markers). These data determine adequacy of herd size, genetic diversity, and historic characteristics. WHB Specialists would collect a minimum sample size of 25 hair samples from both mares and stallions in a ratio similar to the sex ratio released. Age would not be a defining factor in determining which animals to sample. Samples would be sent to Texas A&M University for analysis.

2) Herd Health and Viability Data Collection

WHB Specialists would document information related to age, sex, color, overall health, pregnancy, or nursing status from each animal captured. An estimate of the number of horses evading capture would also be recorded. Information on reproduction would be collected to the extent possible, through documentation of the wild horses captured during the gather, and the age of those released following the gather.

3) Characteristics

WHB Specialists would record color and size of the animals, and any characteristics as to type would be noted, if determined. Any incidence of negative genetic traits (parrot mouth, club foot etc.) or other abnormalities would be noted as well.

4) Condition Class

A body condition class score would be recorded based on the Henneke System. This would be recorded for the population in general and/or for specific animals if necessary.

E. Euthanasia

The Authorized Office (or designee) will make decisions regarding euthanasia, in accordance with BLM policy as expressed in Washington Office Instructional Memorandum No. 2009-041. A DVM may be called to make a diagnosis and final determination. Current BLM SOP is to have a DVM from APHIS on site throughout the gather to observe animal health and condition and provide input to BLM staff regarding the potential need to euthanize wild horses on gathers. Euthanasia shall be done by the most humane method available. Authority for humane

euthanasia of wild horses or burros is provided by the Wild Free-Roaming Horses and Burros Act of1971, Section 3(b)(2)(A), 43 CFR 4730.1, BLM Manual 4730 - Euthanasia of Wild horses and Burros and Disposal of Remains. The following are excerpted from IM 2009-41:

A Bureau of Land Management (BLM) authorized officer may authorize the euthanasia of a wild horse or Burro in field situations (includes free-roaming horses and burros encountered during gather operations) as well as short- and long-term wild horse and Burro holding facilities with any of the following conditions:
(1) Displays a hopeless prognosis for life;
(2) suffers from a chronic or incurable disease, injury or serious physical defect; (includes severe tooth loss or wear, severe club feet, and other severe acquired or congenital abnormalities)
(3) would require continuous treatment for the relief of pain and suffering in a domestic setting;
(4) is incapable of maintaining a Henneke body condition score greater than two, in its present environment;
(5) has an acute or chronic injury, physical defect or lameness that would not allow the animal to live and interact with other horses or burros , keep up with its peers or exhibit behaviors which may be considered essential for an acceptable quality of life constantly or for the foreseeable future;
(6) suffers an acute or chronic infectious disease where State or Federal animal health officials order the humane destruction of the animal as a disease control measure.

There are three circumstances where the authority for euthanasia would be applied in a field situation:
(A) If an animal suffers from a condition as described in 1-6 above that causes acute pain or suffering and immediate euthanasia would be an act of mercy, the authorized officer has the authority and the obligation to promptly euthanize the animal. If the animal is euthanized during a gather operation, the authorized officer will describe the animal''s condition and report the action using the gather report in the comment section that summarizes gather operations (See attachment 1). If the euthanasia is performed during routine monitoring, the Field Manager will be notified of the incident as soon as practical after returning from the field.

(B) Older wild horses and burros encountered during gather operations should be released if, in the opinion of the authorized officer, the criteria described in 1-6 above for euthanasia do not apply, but the animals would not tolerate the stress of transportation, adoption preparation, or holding and may survive if returned to the range. This may include older animals with significant tooth wear or tooth loss that have a Henneke body condition score greater than two. However, if the authorized officer has inspected the animal''s teeth and feels the animal''s quality of life will suffer and include health problems due to dental abnormalities, significant tooth wear or tooth loss; the animal should be euthanized as an act of mercy.

(C) If an animal suffers from any of the conditions listed in 1-6 above, but is not in acute pain, the authorized officer has the authority to euthanize the animal in a humane manner.

I. Special Stipulations

1) Private landowners or the proper administering agency(s) would be contacted and authorization obtained prior to setting up capture corrals on any lands which are not administered by BLM. Wherever possible, capture sites would be constructed in such a manner as to not block vehicular access on existing roads.

2) Capture sites would be constructed so that no riparian vegetation is contained within them. No vehicles would be operated on riparian vegetation or on saturated soils associated with riparian/wetland areas.

3) The helicopter would avoid eagles and other raptors, and would not be flown repeatedly over any identified active raptor nests. No unnecessary flying would occur over big game on their winter ranges or active fawning/calving grounds during the period of use.

4) Standard operating procedures in the site establishment and construction of capture sites will avoid adverse impacts from capture site construction or operation to wildlife species, including threatened, endangered, or sensitive species.

5) Capture sites and sorting/holding facility

No personnel working at gather sites may excavate, remove, damage, or otherwise alter or deface or attempt to excavate, remove, damage or otherwise alter or deface any archaeological resource located on public lands or Tribal lands.

Prior to setting up a trap or temporary holding facility, BLM will conduct all necessary surveys (archaeological, T&E, etc). All proposed site(s) must be inspected by a government archaeologist. Once archaeological survey has been conducted, the trap or temporary holding facility may be set up. Said surveys shall be arranged for by the COR, PI, or other BLM employees.

Gather sites and temporary holding facilities would be constructed outside the RHCA.

Locations would be placed only in areas that have been surveyed and reviewed for potential impacts to cultural resources. Capture site capture sites capture sites. capture sites and sorting/holding facilities

Wilderness Study Areas: When gathering wild horses from within Wilderness Study Areas (WSAs), applicable policy will be strictly adhered to. Only approved roads will be traveled on. A Wilderness Specialist or designee would be present to ensure that only inventoried ways or cherry stemmed roads are traveled on by vehicles within the WSA.

Capture sites and sorting/holding facilities will be constructed outside of weed infested areas to limit the spread of weedy species.

Appendix B: Standard Operating Procedures for Wild Horse and Horse Gathers

Gathers are conducted by utilizing contractors from the Wild Horse Gathers-Western States Contract, or BLM personnel. The following procedures for gathering and handling wild horses would apply whether a contractor or BLM personnel conduct a gather. For helicopter gathers conducted by BLM personnel, gather operations will be conducted in conformance with the *Wild Horse Aviation Management Handbook* H-4740-1 (January 2009).

Prior to any gathering operation, the BLM will provide for a pre-capture evaluation of existing conditions in the gather area(s). The evaluation will include animal conditions, prevailing temperatures, snow depth, drought conditions, soil conditions, road conditions, and a topographic map with wilderness boundaries, the location of fences, other physical barriers, and acceptable capture locations in relation to animal distribution. The evaluation will determine whether the proposed activities will necessitate the presence of a licensed DVM during operations. If it is determined that a large number of animals may need to be euthanized or capture operations could be facilitated by a DVM, these services would be arranged before the capture would proceed. The contractor will be apprised of all conditions and will be given instructions regarding the capture and handling of animals to ensure their health and welfare is protected. Capture sites and temporary sorting/holding facilities will be located to reduce the likelihood of injury and stress to the animals, and to minimize potential damage to the natural resources of the area. Wherever possible, capture sites would be located on or near existing roads to limit ground disturbance.

All capture sites and sorting/holding facility locations must be approved by the Authorized Officer prior to construction. All capture sites and sorting/holding facilities not located on public land must have prior written approval of the landowner.

Capture sites would be located to cause as little injury and stress to the animals, and as little damage to the natural resources of the area, as possible. Sites would be located on or near existing roads. Additional capture sites may be required, as determined by the Authorized Officer, to relieve stress to the animals caused by specific conditions at the time of the gather (i.e. dust, rocky terrain, temperatures, etc.).

The primary capture methods used in the performance of gather operations include:
1. Helicopter Assisted Gathering. This capture method involves utilizing a helicopter to direct wild horses into a temporary corral.
2. Helicopter Assisted Roping. This capture method involves utilizing a helicopter to herd wild horses or burros to ropers on horseback.
3. Bait Trapping. This capture method involves utilizing bait (food/mineral) to lure wild horses into a temporary corral.

A. Capture Methods used in the Performance of Gather Contract Operations

1. The primary concern of the contractor is the safe and humane handling of all animals captured. All capture attempts shall incorporate the following:

All capture sites and sorting/holding facilities locations must be approved by the Contracting Officer's Representative (COR) and/or the Project Inspector (PI) prior to construction. The Contractor may also be required to change or move trap locations as determined by the COR/PI. All traps and sorting/holding facilities not located on public land must have prior written approval of the landowner.

2. The rate of movement and distance the animals travel shall not exceed limitations set by the COR/PI who would consider terrain, physical barriers, weather, condition of the animals and other factors. Under normal circumstances this travel should not exceed 10 miles and may be much less dependent on existing conditions (i.e. ground conditions, animal health, extreme temperature (high and low)).

3. All traps, wings, and sorting/holding facilities shall be constructed, maintained and operated to handle the animals in a safe and humane manner and be in accordance with the following:

    a. Captures sites and sorting/holding facilities shall be constructed of portable panels, the top of which shall not be less than 72 inches high for horses and 60 inches for burros, and the bottom rail of which shall not be more than 12 inches from ground level. All traps and sorting/holding facilities shall be oval or round in design.

    b. All loading chute sides shall be a minimum of 6 feet high and shall be fully covered, plywood, metal without holes larger than 2”x4”.

    c. All runways shall be a minimum of 30 feet long and a minimum of 6 feet high for horses, and 5 feet high for burros, and shall be covered with plywood, burlap, plastic snow fence or like material a minimum of 1 foot to 5 feet above ground level for burros and 1 foot to 6 feet for horses. The location of the government furnished portable fly chute to restrain, age, or provide additional care for the animals shall be placed in the runway in a manner as instructed by or in concurrence with the COR/PI.

    d. All crowding pens including the gates leading to the runways shall be covered with a material which prevents the animals from seeing out (plywood, burlap, plastic snow fence, etc.) and shall be covered a minimum of 1 foot to 5 feet above ground level for burros and 2 feet to 6 feet for horses

    e. All pens and runways used for the movement and handling of animals shall be connected with hinged self-locking or sliding gates.

4. No modification of existing fences would be made without authorization from the COR/PI. The Contractor shall be responsible for restoration of any fence modification which he has made.

5. When dust conditions occur within or adjacent to the trap or sorting/holding facility, the

Contractor shall be required to wet down the ground with water.

6. Alternate pens, within the sorting/holding facility shall be furnished by the Contractor to separate mares or jennies with small foals, sick and injured animals, estrays or other animals the COR determines need to be housed in a separate pen from the other animals. Animals shall be sorted as to age, number, size, temperament, sex, and condition when in the sorting/holding facility so as to minimize, to the extent possible, injury due to fighting and trampling. Under normal conditions, the government would require that animals be restrained for the purpose of determining an animal's age, sex, or other necessary procedures. In these instances, a portable restraining chute may be necessary and would be provided by the government. Alternate pens shall be furnished by the Contractor to hold animals if the specific gathering requires that animals be released back into the capture area(s). In areas requiring one or more satellite traps, and where a centralized sorting/holding facility is utilized, the contractor may be required to provide additional sorting/holding facility to segregate animals transported from remote locations so they may be returned to their traditional ranges. Either segregation or temporary marking and later segregation would be at the discretion of the COR.

7. The Contractor shall provide animals held in the traps and/or sorting/holding facilities with a continuous supply of fresh clean water at a minimum rate of 10 gallons per animal per day. Animals held for 10 hours or more in the traps or sorting/holding facilities shall be provided good quality hay at the rate of not less than two pounds of hay per 100 pounds of estimated body weight per day. The contractor would supply certified weed free hay if required by State, County, and Federal regulation.

8. It is the responsibility of the Contractor to provide security to prevent loss, injury or death of captured animals until delivery to final destination.

9. The Contractor shall restrain sick or injured animals if treatment is necessary. The COR/PI would determine if animals must be euthanized and provide for the destruction of such animals. The Contractor may be required to humanely euthanize animals in the field and to dispose of the carcasses as directed by the COR/PI.

10. Animals shall be transported to their final destination from temporary sorting/holding facilities as quickly as possible after capture unless prior approval is granted by the COR for unusual circumstances. Animals to be released back into the CHMA following gather operations may be held up to 21 days or as directed by the COR. Animals shall not be held in traps and/or temporary sorting/holding facilities on days when there is no work being conducted except as specified by the COR. The Contractor shall schedule shipments of animals to arrive at final destination between 7:00 a.m. and 4:00 p.m. No shipments shall be scheduled to arrive at final destination on Sunday and Federal holidays, unless prior approval has been obtained by the COR. Animals shall not be allowed to remain standing on trucks while not in transport for a combined period of greater than three (3) hours in any 24 hour period. Animals that are to be released back into the capture area may need to be transported back to the original trap site. This determination would be at the discretion of the COR/PI or Field Office horse specialist.

B. Capture Methods That May Be Used in the Performance of a Gather

1. Capture attempts may be accomplished by utilizing bait (food/mineral) to lure animals into a temporary trap. If this capture method is selected, the following applies:

    a. Finger gates shall not be constructed of materials such as "T" posts, sharpened willows, etc., that may be injurious to animals.

    b. All trigger and/or trip gate devices must be approved by the COR/PI prior to capture of animals.

    c. Traps shall be checked a minimum of once every 10 hours.

2. Capture attempts may be accomplished by utilizing a helicopter to drive animals into a temporary trap. If the contractor selects this method the following applies:

    a. A minimum of two saddle-horses shall be immediately available at the trap site to accomplish roping if necessary. Roping shall be done as determined by the COR/PI. Under no circumstances shall animals be tied down for more than one half hour.

    b. The contractor shall assure that foals shall not be left behind, and orphaned.

3. Capture attempts may be accomplished by utilizing a helicopter to drive animals to ropers. If the contractor, with the approval of the COR/PI, selects this method the following applies:

    a. Under no circumstances shall animals be tied down for more than one hour.

    b. The contractor shall assure that foals shall not be left behind, or orphaned.

    c. The rate of movement and distance the animals travel shall not exceed limitations set by the COR/PI who would consider terrain, physical barriers, weather, condition of the animals and other factors.

C. Use of Motorized Equipment

1. All motorized equipment employed in the transportation of captured animals shall be in compliance with appropriate State and Federal laws and regulations applicable to the humane transportation of animals. The Contractor shall provide the COR/PI with a current safety inspection (less than one year old) for all motorized equipment and tractor-trailers used to transport animals to final destination.

2. All motorized equipment, tractor-trailers, and stock trailers shall be in good repair, of adequate rated capacity, and operated so as to ensure that captured animals are transported without undue risk or injury. Equipment will need to be washed to remove invasive species seed.

3. Only tractor-trailers or stock trailers with a covered top shall be allowed for transporting animals from capture site site(s) to temporary sorting/holding facilities, and from temporary sorting/holding facilities to final destination(s). Sides or stock racks of all trailers used for transporting animals shall be a minimum height of 6 feet 6 inches from the floor. Single deck tractor-trailers 40 feet or longer shall have two (2) partition gates providing three (3) compartments within the trailer to separate animals. Tractor-trailers less than 40 feet shall have at least one partition gate providing two (2) compartments within the trailer to separate the animals. Compartments in all tractor-trailers shall be of equal size plus or minus 10 percent. Each partition shall be a minimum of 6 feet high and shall have a minimum 5 foot wide swinging gate. The use of double deck tractor-trailers is unacceptable and shall not be allowed.

4. All tractor-trailers used to transport animals to final destination(s) shall be equipped with at least one (1) door at the rear end of the trailer, which is capable of sliding either horizontally or vertically. The rear door(s) of tractor-trailers and stock trailers must be capable of opening the full width of the trailer. Panels facing the inside of all trailers must be free of sharp edges, protrusions or holes that could cause injury to the animals. The material facing the inside of all trailers must be strong enough so that the animals cannot push their hooves through the side. Final approval of tractor-trailers and stock trailers used to transport animals shall be held by the COR/PI.

5. Floors of tractor-trailers, stock trailers and loading chutes shall be covered and maintained with wood shavings to prevent the animals from slipping.

6. Animals to be loaded and transported in any trailer shall be as directed by the COR/PI and may include limitations on numbers according to age, size, sex, temperament and animal condition. The following minimum square feet per animal shall be allowed in all trailers:

11 square feet per adult horse (1.4 linear foot in an 8 foot wide trailer);
8 square feet per adult burro (1.0 linear foot in an 8 foot wide trailer);
6 square feet per horse foal (.75 linear foot in an 8 foot wide trailer);
4 square feet per burro foal (.50 linear feet in an 8 foot wide trailer).

7. The COR/PI shall consider the condition and size of the animals, weather conditions, distance to be transported, or other factors when planning for the movement of captured animals. The COR/PI shall provide for any brand and/or inspection services required for the captured animals.

8. If the COR/PI determines that dust conditions are such that the animals could be endangered during transportation, the Contractor will be instructed to adjust speed of transporting vehicles.

D. Treatment of Injured or Sick; Disposition of Terminal Animals

The contractor would restrain sick or injured animals if treatment is necessary. A veterinarian may be called to make a diagnosis and final determination. Destruction would be done by the most humane method available. Authority for humane destruction of wild horses is provided by the Wild Free-Roaming Horse and Burro Act of 1971, Section 3(b)(2)(A), 43 CFR 4730.1, BLM

Manual 4730 - Destruction of Wild Horses and Burros and Disposal of Remains, and is in accordance with BLM policy as expressed in Instructional Memorandum No. 98-141.

The Authorized Officer would determine if injured animals must be destroyed and provide for destruction of such animals. The contractor may be required to dispose of the carcasses as directed by the Authorized Officer.

The carcasses of the animals that die or must be destroyed as a result of any infectious, contagious, or parasitic disease would be disposed of by burial to a depth of at least 3 feet.

The carcasses of the animals that must be destroyed as a result of age, injury, lameness, or noncontagious disease or illness would be disposed of by removing them from the capture site or sorting/holding corral and placing them in an inconspicuous location to minimize visual impacts. Carcasses would not be placed in drainages regardless of drainage size or downstream destination.

E. Safety and Communications

1. The Contractor shall have the means to communicate with the COR/PI and all contractor personnel engaged in the capture of wild horses utilizing a VHF/FM Transceiver or VHF/FM portable Two-Way radio. If communications are ineffective the government will take steps necessary to protect the welfare of the animals.

    a. The proper operation, service and maintenance of all contractor-furnished property is the responsibility of the Contractor. The BLM reserves the right to remove from service any contractor personnel or contractor-furnished equipment which, in the opinion of the contracting officer or COR/PI violate contract rules, are unsafe or otherwise unsatisfactory. In this event, the Contractor will be notified in writing to furnish replacement personnel or equipment within 48 hours of notification. All such replacements must be approved in advance of operation by the Contracting Officer or his/her representative.

    b. The Contractor shall obtain the necessary FCC licenses for the radio system

    c. All accidents occurring during the performance of any task order shall be immediately reported to the COR/PI.

2. Should the contractor choose to utilize a helicopter the following will apply:

    a. The Contractor must operate in compliance with Federal Aviation Regulations, Part 91. Pilots provided by the Contractor shall comply with the Contractor's Federal Aviation Certificates, applicable regulations of the State in which the gather is located.

    b. Fueling operations shall not take place within 1,000 feet of animals.

F. Site Clearances

Personnel working at gather sites will be advised of the illegality of collecting artifacts. Prior to setting up a capture site or temporary sorting/holding facility on a site not previously cleared or disturbed, BLM will conduct all necessary clearances (archaeological, T&E, etc). All proposed site(s) must be inspected by a government archaeologist. Once archaeological clearance has been obtained, the capture site or temporary sorting/holding facility may be set up. Said clearance shall be arranged for by the COR, PI, or other BLM employees.

No personnel working at gather sites may excavate, remove, damage, or otherwise alter or deface or attempt to excavate, remove, damage or otherwise alter or deface any archaeological resource located on public lands.

New capture sites and temporary holding/sorting facilities would be constructed outside RHCA or weed infested areas.

G. Public Participation

Opportunities for public viewing (i.e. media, interested public) of gather operations will be made available to the extent possible; however, the primary considerations will be to protect the health, safety, and welfare of the animals being gathered and the personnel involved. The public must adhere to guidance from the on-site BLM representatives. It is BLM policy that the public will not be allowed to come into direct contact with wild horses or burros being held in BLM facilities. Only authorized BLM personnel or contractors may enter the corrals or directly handle the animals. The general public may not enter the corrals, climb on or lean through corrals, or directly handle the animals at any time or for any reason during BLM operations (refer to Appendix F and G).

H. Responsibility and Lines of Communication

Incident Command

Chris Robbins—Idaho Wild Horse and Burro State Lead

Contracting Officer's Representative

Kevin Lloyd—Challis Field Office Wild Horse and Burro Specialist

Alternate Contracting Officer's Representative

Scott Fleur—Lander (WY) Field Office Wild Horse and Burro Specialist

Project Inspector

Kent Benson– Burley Field Office BLM Range Technician

The Contracting Officer‘s Representatives (CORs) and the project inspectors (PIs) have the direct responsibility to ensure the Contractor‘s compliance with the contract stipulations. Kevin Lloyd, Challis Field Office WH&B Specialist would serve as the primary COR. Todd Kuck, CFO Field Manager, other CFO employees, Idaho Falls District employees and members of the Idaho Wild Horse Team will take an active role to ensure the appropriate lines of communication are established between the field, Field Office, State Office, National Program Office, and BLM

Sorting/holding Facility offices. All employees involved in the gather operations will keep the best interests of the animals at the forefront at all times.

All publicity, formal public contact and inquiries will be handled through the Idaho State Office and the Idaho Wild Horse Team Public Affairs Officer. These individuals will be the primary contact and will coordinate with the COR on any inquiries.

The COR would coordinate with the contractor and the BLM Corrals to ensure animals are being transported from the sorting/holding facility in a safe and humane manner and are arriving in good condition.

The contract specifications require humane treatment and care of the animals during removal operations. These specifications are designed to minimize the risk of injury and death during and after capture of the animals. The specifications would be vigorously enforced.

Should the Contractor show negligence and/or not perform according to contract stipulations, he would be issued written instructions, stop work orders, or defaulted by the COR.

I. Additional requirements for personnel conducting gather operations also include:

1. Electric prods (hotshots) would not be used routinely on horses. They can be used when animal or human safety is in jeopardy or as a last resort. Handlers do not constantly carry prods. Prods are picked up only when necessary and then put away. Electric prods are never applied to sensitive areas such as the eyes.
2. Electric prod use will not be disguised, but used openly and transparently.
3. Handling aids, including electric prods and flags will not be used abusively.
4. Flagging will be used strategically, as excessive flagging desensitizes the animal and becomes useless if used too much.
5. Gates and doors will not be deliberately slammed or shut on horses or burros passing through.
6. Excessive yelling and unnecessary noises will not be utilized in the loading and unloading process.
7. There will be no hitting, kicking, or striking a horse.
8. Loading or unloading of transport vehicles is performed during daylight hours, or supplemental light will be provided in the area to facilitate visibility.
9. Holes, gaps, or openings will be eliminated in the loading/unloading area to avoid injury.
10. Transport vehicles will be properly aligned with the loading/unloading ramps or docks. No gaps will exist between the unloading/loading docks or ramps and the bottom or floor of the trailer's exit. No gaps will exist between the trailer and the side walls of the unloading area, whereby a horse's limbs or head can become stuck or injured.

Appendix C Standard Operating Procedures for Population-level Fertility Control Treatments

One-year liquid vaccine: The following implementation and monitoring requirements are part of the Proposed Action:

1. PZP vaccine would be administered through darting by trained BLM personnel or collaborating research partners only. For any darting operation, the designated personnel must have successfully completed a nationally recognized wildlife darting course and who have documented and successful experience darting wildlife under field conditions.
2. Mares that have never been treated would receive 0.5 cc of PZP vaccine emulsified with 0.5 cc of Freund's Modified Adjuvant (FMA) and loaded into darts at the time a decision has been made to dart a specific mare. Mares identified for re-treatment receive 0.5 cc of the PZP vaccine emulsified with 0.5 cc of Freund's Incomplete Adjuvant (FIA).
3. The liquid dose of PZP vaccine is administered using 1.0 cc Pneu-Darts with 1.5" barbless needles fired from either Dan Inject® or Pneu-Dart® capture gun.
4. Only designated darters would mix the vaccine/adjuvant and prepare the emulsion. Vaccine-adjuvant emulsion would be loaded into darts at the darting site and delivered by means of a capture gun.
5. Delivery of the vaccine would be by intramuscular injection into the left or right hip/gluteal muscles while the mare is standing still.
6. Safety for both humans and the horse is the foremost consideration in deciding to dart a mare. The Dan Inject® gun would not be used at ranges in excess of 30 m while the Pneu-Dart® capture gun would not be used over 50 m, and no attempt would be taken when other persons are within a 30-m radius of the target animal.
7. No attempts would be taken in high wind or when the horse is standing at an angle where the dart could miss the hip/gluteal region and hit the rib cage. The ideal is when the dart would strike the skin of the horse at a perfect 90° angle.
8. If a loaded dart is not used within two hours of the time of loading, the contents would be transferred to a new dart before attempting another horse. If the dart is not used before the end of the day, it would be stored under refrigeration and the contents transferred to another dart the next day. Refrigerated darts would not be used in the field.
9. No more than two people should be present at the time of a darting. The second person is responsible for locating fired darts. The second person should also be responsible for identifying the horse and keeping onlookers at a safe distance.
10. To the extent possible, all darting would be carried out in a discrete manner. However, if darting is to be done within view of non-participants or members of the public, an explanation of the nature of the project would be carried out either immediately before or after the darting.
11. Attempts would be made to recover all darts. To the extent possible, all darts which are discharged and drop from the horse at the darting site would be recovered before another darting occurs. In exceptional situations, the site of a lost dart may be noted and marked, and recovery efforts made at a later time. All discharged darts would be examined after recovery in order to determine if the charge fired and the plunger fully expelled the vaccine.

22-month time-release pelleted vaccine:
The following implementation and monitoring requirements are part of the Proposed Action:

1. PZP vaccine would be administered only by trained BLM personnel or collaborating research partners.
2. Mares that have never been treated would receive 0.5 cc of PZP vaccine emulsified with 0.5 cc of Freund‘s Modified Adjuvant (FMA). Mares identified for re-treatment receive 0.5 cc of the PZP vaccine emulsified with 0.5 cc of Freund‘s Incomplete Adjuvant (FIA).
3. The fertility control drug is administered with two separate injections: (1) a liquid dose of PZP is administered using an 18-gauge needle primarily by hand injection; (2) the pellets are preloaded into a 14-gauge needle. These are delivered using a modified syringe and jabstick to inject the pellets into the gluteal muscles of the mares being returned to the range. The pellets are designed to release PZP over time similar to a time-release cold capsule.
4. Delivery of the vaccine would be by intramuscular injection into the gluteal muscles while the mare is restrained in a working chute. The primer would consist of 0.5 cc of liquid PZP emulsified with 0.5 cc of Freunds Modified Adjuvant (FMA). The pellets would be loaded into the jabstick for the second injection. With each injection, the liquid or pellets would be injected into the left hind quarters of the mare, above the imaginary line that connects the point of the hip (hook bone) and the point of the buttocks (pin bone).
5. In the future, the vaccine may be administered remotely using an approved long range darting protocol and delivery system if or when that technology is developed.
6. All treated mares will be freeze-marked on the hip or neck CHMA to positively identify the treated animals during the research project and during subsequent gathers. Within the Challis CHMA, treated mares are freeze branded with an AA on their left (right?) hip.

Monitoring and Tracking of Treatments:
1. At a minimum, estimation of population growth rates using helicopter or fixed-wing surveys will be conducted before any subsequent gather. During these surveys it is not necessary to identify which foals were born to which mares; only an estimate of population growth is needed (i.e. # of foals to # of adults).
2. Population growth rates of herds (CHMA is not selected for intensive monitoring) selected for intensive monitoring will be estimated every year post-treatment using helicopter or fixed-wing surveys. During these surveys it is not necessary to identify which foals were born to which mares, only an estimate of population growth is needed (i.e. # of foals to # of adults). If, during routine CHMA field monitoring (on-the-ground), data describing mare to foal ratios can be collected, these data should also be shared with the NPO for possible analysis by the USGS.
3. A PZP Application Data sheet will be used by field applicators to record all pertinent data relating to identification of the mare (including photographs if mares are not freeze-marked) and date of treatment. Each applicator will submit a PZP Application Report and accompanying narrative and data sheets will be forwarded to the NPO (Reno, Nevada). A copy of the form and data sheets and any photos taken will be maintained at the field office.
4. A tracking system will be maintained by NPO detailing the quantity of PZP issued, the quantity used, disposition of any unused PZP, the number of treated mares by HMA, field office, and State along with the freeze-mark(s) applied by HMA and date.

Appendix D: WinEquus Population Modeling Summary

Summary of Genetic Viability and Population Modeling in Wild Horse Herds

Genetic Viability
The concept of Minimum Viable Populations (MVP), or the minimum number of breeding individuals required for a population to survive over a period of time has been a central issue to conservation biology for years. The BLM is now taking MVP into consideration in the management of its wild horse herds in response to the challenge of balancing wild horse impacts on their ecosystem with a herd size large enough to constitute a viable population size. A wild horse population managed at numbers low enough to prevent ecological damage may pose problems to the long-term health and genetic diversity of a herd.

Genetic diversity, within wild horse and burro populations, refers to the entire complement of genetic material representative of all individuals (or a sample of individuals) from within the population. Some populations may possess genetic uniformity to a certain "type" or breed of horse, but management interests are specific to maintaining a maximum diversity of genetic material which appears representative of each herd. Promotion of diversity will minimize the effects of genetic drift, or the random loss of genetic material due to mating processes, and maximize genetic health of the herds.

The genetic effective population size (Ne) is a measure of the total number of mares and stallions which contribute genetically, through successful breeding, to the next generation. Although no standard goal for Ne currently exists for wild horse and burro herds, a goal of Ne=50, which comes from domestic breeding guidelines, can be conservatively applied**.** Populations, where Ne is calculated to be less than 50, may experience higher rates of loss of genetic diversity than would be considered acceptable under recommended management goals.

Viable management Alternatives for conserving genetic diversity within managed wild horse herds may take several forms. Some options to be considered might include: altering population age structure (through removals) to promote higher numbers of reproductively-successful animals; altering breeding sex ratios (through removals) to encourage more breeding males; increasing generation intervals (and reducing the rate of loss of genetic material) by removing (or sterilizing) younger versus older mares; and/or introducing breeding animals periodically from other genetically similar herds to help in conservation efforts. In this last scenario, only one or two breeding animals per generation (~10 years) would need to be introduced in order to maintain the genetic resources in small populations of less than 100 animals.

Population Modeling
The **Wild Horse Population Model** (*WinEquus version 1.40*) developed by Dr. Steve Jenkins was used to estimate the population growth and size of herds five years after the gather. There are three data sets from three Herd Management Areas (Garfield, Granites, and Pryor Mountain) built into and available for use in the Jenkins Model. An infinite number of data sets from other sources can also be entered into the model for local herds. Most population projections are based on the Garfield data. These data are the best available for many areas and are based on substantial field work and research. The model's projections using the Garfield data are very

close to what actually occurs in the herds. BLM has not conducted an independent analysis to compare the model's projections with observed growth rates. The Jenkins Model is a tool that BLM uses compare the relative effects of one proposed management action to other alternative management actions including removals and fertility control. Dean Bolstad stated "*We recognize that some of the data in the model may not be exact for any given herd management area, but the model has been useful to approximate the effects of management actions and to compare alternatives*". (Bolstad personal communication 2009)

The wild horse population data used in the statistical analysis modeling was extrapolated from the 2009 gather/removal and population inventory, including numbers, age and sex structure of the remaining horses in the CHMA as well as the ones released back into CHMA.

Sex ratio at Birth: 43% Females 57% Males

The following percent effectiveness of fertility control was utilized in the population modeling for Alternative I:

Year 1: 94%, Year 2: 82%, Year 3: 68%

The environmental and demographic model option was selected as a means to project population growth while weighing both environmental and demographic variables during 'good' and 'bad' years. Results of the Jenkins population model are not considered a 'prediction' of what will happen to the herds in the future. Results of the model are being used as an aid to evaluate the management practices that are identified in this document and to project population growth.
The modeling analysis made the following assumptions for all Alternatives:
1. The current age selection policy would continue through the lifetime of the modeling analysis.
2. Gathers would be completed every four years with the herds lowered to AML.
3. The herd would rise to at least the threshold limit prior to a gather.
4. Foals are included in the herd appropriate management level.
5. 85% of the herd can be located during gather operations; 15% are not found.
6. All simulations used the survival and foaling rates supplied with the WinEquus population model for the Garfield Flat HMA.
7. Simulations were run for ten years with 100 trials each.
Assumptions: Population Modeling Criteria/Management Options by Alternative, Proposed Alternative, Fertility Control
Gather interval: regular interval of four years
Gathers for fertility treatment only occur if population exceeds threshold.
Gathers continue after removals to treat additional females to be released.
Percent effectiveness of fertility control: Year 1: 94%, Year 2: 84%, Year 3: 62% (November window).
Percentages of released mares treated: 5-20+: 100%.
100% of 0-4 year olds removed.

The modeling trials are based on Alternatives1, 2 and 5. Alternatives 3 and 4 are too specific for WinEquus to model. It may be expected that were trials conducted the numbers for Alternative 3 numbers would range lower than Alternative 1 and Alternative 4 numbers would range higher than Alternative 1.

Alternative 1-Proposed Action
Remove Wild Horses using selective removal criteria, administer Fertility Control on mares returning to the CHMA and maintaining the 60:40 sex ratio of males to females

Alternative 2-Removal only following the selective removal criteria without the fertility control or skewing the sex ratio

Alternative 3-Removal with fertility control with geldings being released as a non-reproducing component of the wild horse herd

Alternative 4- Removal with fertility control but no sex ratio adjustment

Alternative 5- No Action
Modeling under this alternative shows no management of wild horses where they are allowed to reproduce uncontrolled until natural parameters begin to take effect.

Objectives of Population Modeling
Review of the data output for each of the simulations completed with the population model provided many useful comparisons of the possible outcomes for each Alternative. The creator of the modeling program, Stephen Jenkins stresses that it is important to think about the range of possible outcomes, not just focus on one average or typical trial. Some of the questions that needed to be answered through the modeling include the following:
• Do any of the Alternatives "crash" the population?
• What effect does fertility control have on population growth rate?
• What effects do the different Alternatives have on the average population size?

Population size in ten years
Out of the 100 trials in each simulation run, the model tabulated minimum, average and maximum population sizes. The model was run for a period of ten years from 2009 to 2018, and gives output through 2019 (which is actually eleven years). These numbers are useful to make relative comparisons of the different Alternatives, and potential outcomes under different management options. The data displayed within the Table 26 is broken down into different levels. The 10th percentile, 90th percentile and the average are all shown on the Table 26. This output, together with the summary graph of population sizes, is probably the most important representation of the results of the program in terms of assessing the effects of the management plan because it shows not only expected average results but also extreme results that might be possible. The data is for all horses from 0 to 20 years of age.

None of the results obtained for any of the Alternatives indicate that a crash of the population would occur if the Alternative were implemented.

Table 26. Population Size Graph

Modeling Statistics CHMA	Alternative 1 Proposed Action	Alternative 2 Removal Without Additional Population Controls	No Action Alternative 5
Population in Year One	185	185	322
Median Growth Rate	14.5	17.4	16.9
Average Population	204	234	292
10th Percentile	178	212	229
90th Percentile	230	257	362

Alternative 1—Proposed Action
The Proposed Action Alternative includes the gather and removal of horses as well as implementing fertility control and skewing the sex ratios 60:40 in favor of males.

Figure 3. Management Efforts of Gathering Approximately Every Three Years

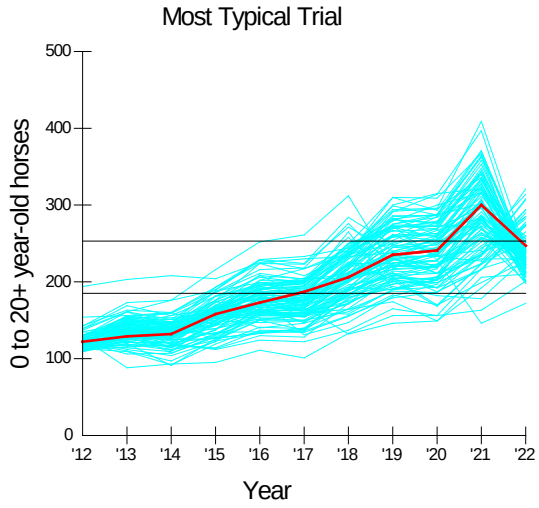

Figure 3 above shows management efforts including gatherings approximately every three years.

Figure 4. Maximum, Average, and Minimum Growth Rates of the Proposed Action

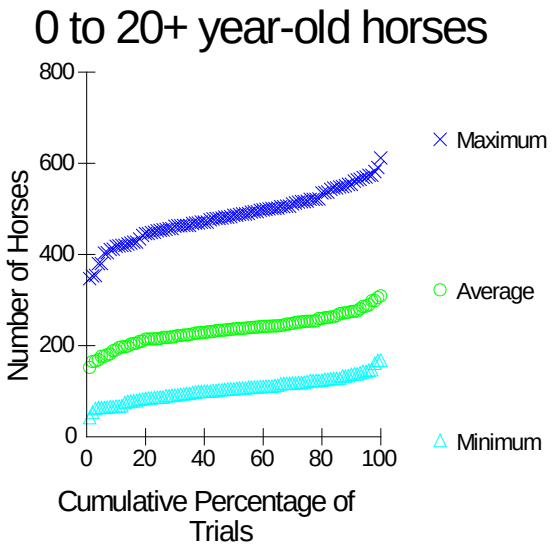

Figure 4 above shows the maximum, average, and minimum growth rate with the proposed action management tools.

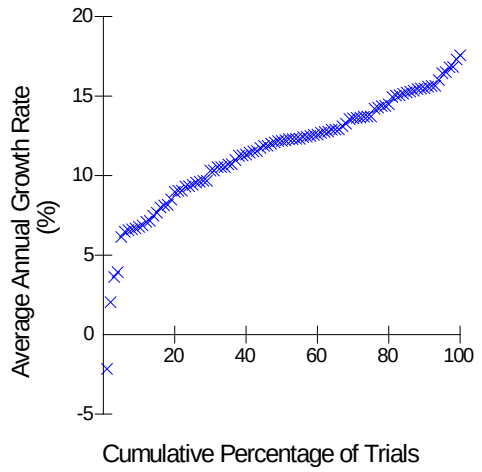


Population Sizes in 11 Years*

	Minimum	Average	Maximum
Lowest Trial	88	137	201
10th Percentile	110	166	256
25th Percentile	111	178	274
Median Tria	117	192	296
75th Percentile	124	206	322
90th Percentile	130	218	350
Highest Trial	194	227	409

* 0 to 20+ year-old horses

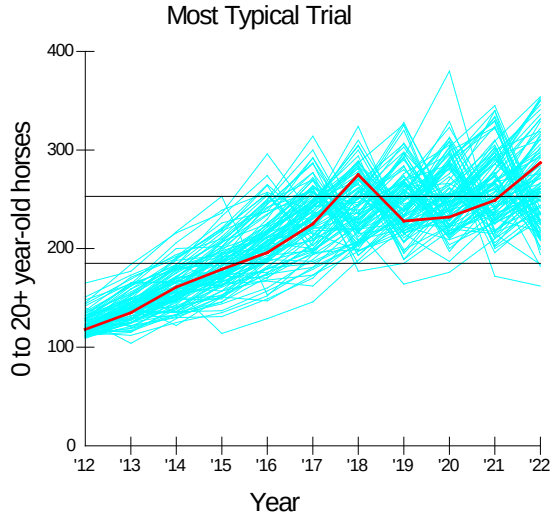
In 11 years and 100 trials, the lowest number of 0 to 20+ year-old horses ever obtained was 88 and the highest was 409. In half the trials, the minimum population size in 11 years was less than 117 and the maximum was less than 296. The average population size across 11 years ranged from 137 to 227.

Figure 5. Cumulative Percentage of Trials with Average Annual Growth Rate of Proposed Action

Average Growth Rate in 10 Years	
Lowest Trial	2.2
10th Percentile	6.8
25th Percentile	9.5
Median Trial	12.2
75th Percentile	14.0
90th Percentile	15.5
Highest Trial	17.6

Alternative 2—Removal Only

Figure 6. Alternative 2 Trial



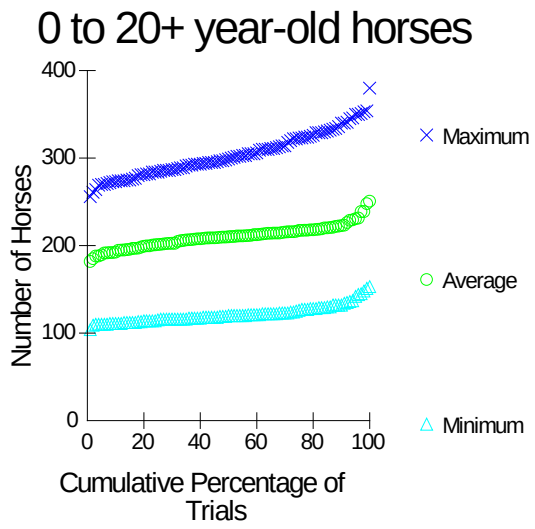


Figure 7. Cumulative Percentage of Trials with Average Annual Growth Rate of Alternative 2

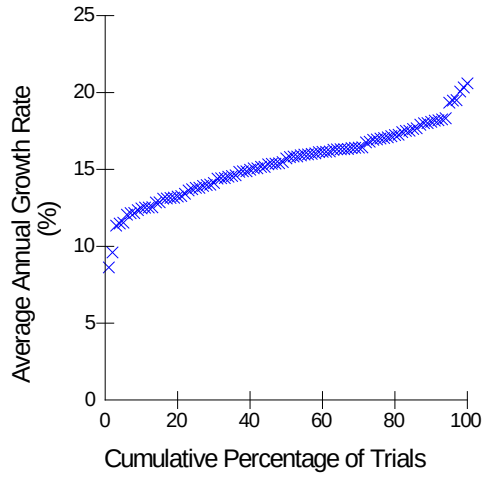


Population Sizes in 11 Years*

	Minimum	Average	Maximum
Lowest Trial	104	182	256
10th Percentile	111	194	274
25th Percentile	116	201	284
Median Trial	120	210	300
75th Percentile	126	217	323
90th Percentile	133	223	340
Highest Trial	153	251	380

* 0 to 20+ year-old horses

In 11 years and 100 trials, the lowest number of 0 to 20+ year-old horses ever obtained was 104 and the highest was 380. In half the trials, the minimum population size in 11 years was less than 120 and the maximum was less than 300. The average population size across 11 years ranged from 182 to 251.

Figure 8. Cumulative Percentage of Trials with Average Annual Growth Rate

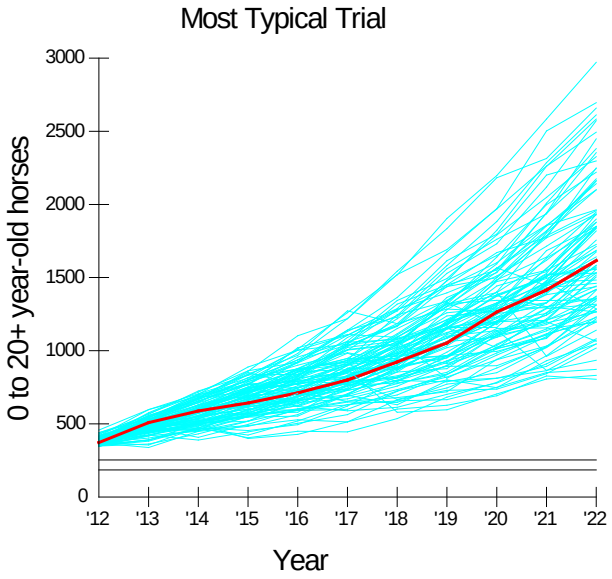
Average Growth Rate in 10 Years	
Lowest Trial	8.6
10th Percentile	12.5
25th Percentile	13.8
Median Trial	15.8
75th Percentile	17.0
90th Percentile	18.1
Highest Trial	20.6

Alternative 5--No Action

No Management is the No Action Alternative where no management of the CHMA would occur to alter the population.

Sex ratio at birth: 57% males
Scaling factors for annual variation: survival probabilities = 1.00, foaling rates = 1.00
Correlation between annual variation in survival probabilities and foaling rates = 0.00
Management by removals and fertility control
Starting year is 2012
Gathering occurs at minimum interval of 3 years
Initial gather year is 0
Gathers for fertility treatment occur regardless of population size.
Gathers do not continue after removals to treat additional females.
Threshold population size for gathers is 0.
Target population size following removals is 0.
Foals are included in AML.
Percent of population that can be gathered = 80%.
Percent effectiveness of fertility control: year 1 is 90%, year 2 is 0%, year 3 is 0%, year 4 is 0%, year 5 is 0%.

Figure 9. Cumulative Percentage of Trials with Average Annual Growth Rate of Alternative 5.



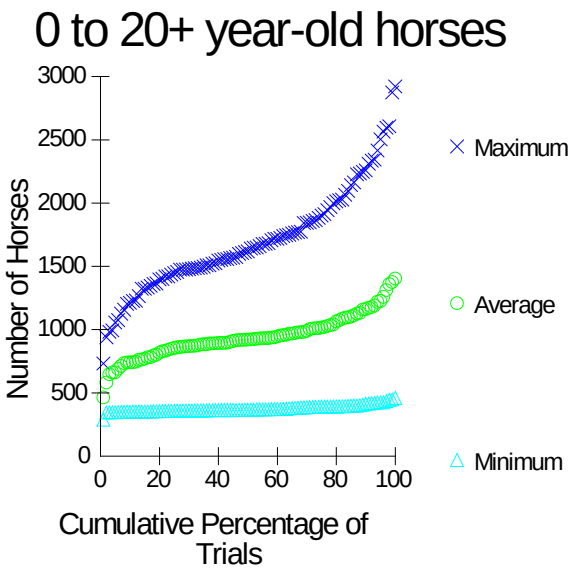


Figure 10. No Management-Typical Trial

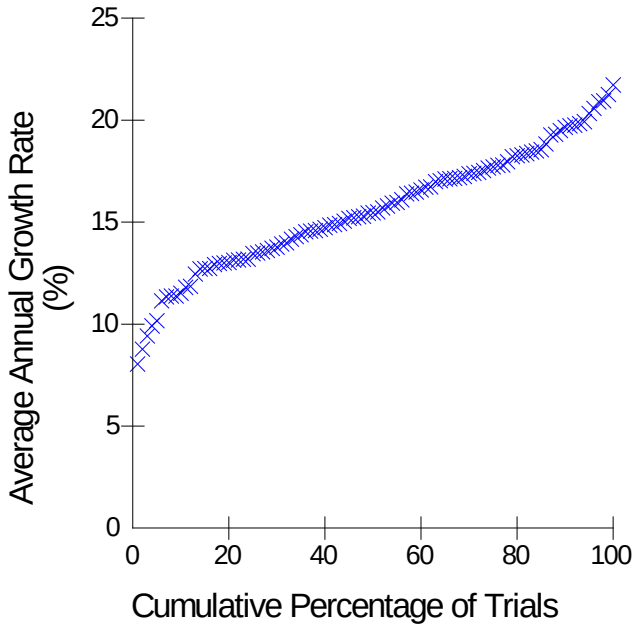

Population Sizes in 11 Years*

	Minimum	Average	Maximum
Lowest Trial	288	463	732
10th Percentile	350	742	1220
25th Percentile	358	856	1451
Median Trial	366	921	1630
75th Percentile	391	1018	1908
90th Percentile	414	1167	2285
Highest Trial	460	1404	2922

* 0 to 20+ year-old horses

In 11 years and 100 trials, the lowest number of 0 to 20+ year-old horses ever obtained was 288 and the highest was 2922. In half the trials, the minimum population size in 11 years was less than 366 and the maximum was less than 1630. The average population size across 11 years ranged from 463 to 1404.

Figure 11. No Management-Population Graph

Average Growth Rate in 10 Years	
Lowest Trial	8.0
10th Percentile	11.7
25th Percentile	13.5
Median Trial	15.5
75th Percentile	17.7
90th Percentile	19.7
Highest Trial	21.7

Average Growth Rates in 10 years

Growth rates were obtained from running the model for 100 trials for four years under management options for each Alternative. As expected, the Alternative implementing fertility control reflects the lowest overall growth rate. The type of gather (gatecut vs. selective removal) seems to have minimal impacts to the growth rates as there are little differences between Alternatives I and 2. The range of growth rates are reasonable and do not indicate that any of the Alternatives would result in growth rates that are so low as to put the population at risk.

Growth Rate Graph

The growth rate graph shows the distribution of average growth rate across all trials in graphical format. Each point on the graph represents one of the 100 trials run for each simulation. The direct effects of removals are not counted in computing annual growth rates, although a selective

removal may change the average foaling rate or survival rate of individuals in the population and may indirectly affect the growth rate. Fertility control was reflected in a reduction of population growth rate compared to the observed rate from previous censuses.
The following graphs illustrate the results obtained from the model for growth rates for each Alternative.

Proposed Alternative I
Population Modeling Summary
To summarize the results obtained by simulating the range of Alternatives for the CHMA wild horse gather, the original questions can be addressed.
• Do any of the Alternatives "crash" the population?

None of the Alternatives indicate that a crash is likely to occur to the population under any of the Alternatives. Minimum population levels and growth rates are all within reasonable levels, and adverse impacts to the population are not likely.
• What effect does fertility control have on population growth rate?

As expected, the Alternative implementing fertility control reflects the lowest overall growth rate of 14.5%.
• What effect do the different Alternatives have on the average population size?

The growth rate does not vary between the different alternatives that do not include fertility control. Growth is similar between Alternative I and Alternative II. Populations of wild horses have the capacity to increase at rates as high as 30% per year. Research has shown that unmanaged populations of wild horses and might eventually stabilize (due to density-dependent regulatory mechanisms) at very high numbers, near what is known as their food-limited ecological carrying capacity. At these levels, however, the herds would show obvious signs of ill-fitness including poor individual animal condition, low birth rates, and high mortality rates in all age classes due to disease and/or increased vulnerability to predation. In addition, supporting range conditions would be noticeably deteriorated, with much of the available habitat showing symptoms of irreparable over-grazing. The CHMA is currently managed to allow the herd to be healthy with strong foal production and survival rates. The model analysis indicates that with fertility control and removals, production rates would decline and the herds could be managed at a four year gather cycle.

Appendix E: Protocol and Ground Rules Daily Visitation Protocol and Ground Rules for the Challis Wild Horse Gather

BLM recognizes and respects the right of interested members of the public and the press to observe the Challis wild horse gather. At the same time, BLM must ensure the health and safety of the public, BLM's employees and contractors, and America's wild horses. Accordingly, BLM developed these rules to maximize the opportunity for reasonable public access to the gather while ensuring that BLM's health and safety responsibilities are fulfilled. Failure to maintain safe distances from operations at the gather and temporary sorting/holding sites could result in members of the public inadvertently getting in the path of the wild horses or gather personnel, thereby placing themselves and others at risk, or causing stress and potential injury to the wild horses.

General Daily Protocol

A Wild Horse Gather Information Phone Line will be set up prior to the gather so the public can call for daily updates on gather information and statistics. Visitors are strongly encouraged to check the phone line the evening before they plan to attend the gather to confirm the gather and their tour of it is indeed taking place the next day as scheduled (weather, mechanical issues or other things may affect this) and to confirm the meeting location.

Visitors must direct their questions/comments to either their designated BLM representative or the BLM spokesperson on site, and not engage other BLM/contractor staff and disrupt their gather duties/responsibilities - professional and respectful behavior is expected of all. BLM may make the BLM staff available during down times for a Q&A session on guided pubic-observation days. However, the contractor and its staff will not be available to answer questions or interact with visitors.

Observers are prohibited from riding in government and contractor vehicles and equipment.

Observers must provide their own 4-wheel drive high clearance vehicle, appropriate shoes, winter clothing, food and water.

Gather operations may be suspended if bad weather conditions create unsafe flying conditions.

BLM will establish one or more observation areas, in the immediate area of the gather and sorting/holding sites, to which individuals will be directed. These areas will be placed so as to maximize the opportunity for public observation while providing for a safe and effective horse gather. The utilization of such observation areas is necessary due to the use and presence of heavy equipment
and aircraft in the gather operation and the critical need to allow BLM personnel and contractors to fully focus on attending to the needs of the wild horses while maintaining a safe environment for all involved. In addition, observation areas will be located so as to protect the wild horses from being spooked, startled or impacted in a manner that results in increased stress.

BLM will delineate observation areas with yellow caution tape (or a similar type of tape or ribbon).

Visitors will be assigned to a specific BLM representative on guided-observation days and must stay with that person at all times.

Visitors are **NOT** permitted to walk around the gather site or temporary sorting/holding facility unaccompanied by their BLM representative.

Observers are prohibited from climbing/trespassing onto or in the trucks, equipment or corrals, which is the private property of the contractor.

When BLM is using a helicopter or other heavy equipment in close proximity to a designated observation area, members of the public may be asked to stay by their vehicle for some time before being directed to an observation area once the use of the helicopter or the heavy machinery is complete.

When given the signal that the helicopter is close to the gather site bringing horses in, visitors must sit down in areas specified by BLM representatives and must not move or talk as the horses are guided into the corral.

Individuals attempting to move outside a designated observation area will be requested to move back to the designated area or to leave the site. Failure to do so may result in citation or arrest. It is important to stay within the designated observation area to safely observe the wild horse gather.

Observers will be polite, professional and respectful to BLM managers and staff and the contractor/employees. Visitors who do not cooperate and follow the rules will be escorted off the gather site by BLM law enforcement personnel, and will be prohibited from participating in any subsequent observation days.

BLM reserves the right to alter these rules based on changes in circumstances that may pose a risk to health, public safety or the safety of wild horses (such as weather, lightening, wildfire, etc.).

Public Observation
Guided public observation will provide for interested members of the public to see the wild horse gather activities at a given site. On this day, BLM attempts to allow the public to get an overall sense of the gather process and has available staff who can answer questions that the public may have. The public may rendezvous at a designated place and may be escorted by BLM representatives to and from the gather site. If not escorted, maps and meeting locations/times will be provided.

The number of guided observation days, and which days they are, will be determined prior to the gather and will be announced through a press release and on the website. Interested observers should RSVP ahead through the BLM-Challis Field Office. A meeting place will be set for each observation day and the RSVP list notified. BLM representatives will escort observers on guided observation days to and from the gather site and temporary sorting/holding facility.

Appendix F: BLM Instruction Memorandum Number 2010-164

UNITED STATES DEPARTMENT OF THE INTERIOR BUREAU OF LAND MANAGEMENT WASHINGTON, D.C. 20240 http://www.blm.gov
July 22, 2010
In Reply Refer To:
4710 (260) P

EMS TRNASMISSION 07/23/2010
Instruction Memorandum No. 2010-164
Expires: 09/30/2011

To: All Field Officials (except Alaska)
From: Assistant Director, Renewable Resources and Planning
Subject: Public Observation of Wild Horse and Burro Gathers

Program Area: Wild Horse and Burro Program

Purpose: The purpose of this Instruction Memorandum (IM) is to establish policy for public observation of wild horse and burro (WH&B) gathers.

Policy/Action: The Bureau of Land Management's (BLM's) policy is to accommodate public requests to observe a gather primarily through advance appointment, on days and at times scheduled by the authorized officer. Planning for one public observation day per week is suggested.

Specific viewing opportunities will be based on the availability of staff with the necessary expertise to safely and effectively host visitors, as well as other gather-specific considerations (e.g., weather, terrain, road access, landownership). The public should be advised that observation days are tentative and may change due to unforeseen circumstances (e.g., weather, wildfire, trap relocation, equipment repair, etc.). To ensure safety, the number of people allowed per observation day will be determined by the District Manager (DM) and/or Field Office Manager (FM) in consultation with the Contracting Officer's Representative/WH&B Specialist (COR) for the gather.

The DM/FM has the primary responsibility for effectively planning and managing public observation of the gather operation. Advance planning will:
· Ensure that the public have opportunities to safely observe wild horse gathers;
· Minimize the potential for disruption of the gather's execution;
· Maximize the safety of the animals, visitors, and the BLM and contractor personnel;
· Provide for successful management of visitors; and
· Ensure preparedness in the event of unanticipated situations.
The authorized officer will consider the following when planning for public observation of WH&B gather operations. Also see Attachment 1 (Best Practices When Planning for Public Observation at Gathers).

A. Safety Requirements
During WH&B gathers, the safety of the animals, the BLM and contractor personnel, and the public is of paramount importance. Because of the inherent risk involved in working with WH&B, the public will not be allowed inside corrals or pens or be in direct contact with the animals. Viewing opportunities during the gather operation must always be maintained at a safe distance (e.g., when animals are being herded into or worked at the trap or temporary sorting/holding facility, including sorting, loading) to assure the safety of the animals, the BLM and contractor personnel, and the public.

Unless an emergency situation exists, the BLM's policy prohibits the transportation of members of the public in Government or Contractor-owned or leased vehicles or equipment. Therefore, observers are responsible for providing their own transportation to and from the gather site and assume all liability for such transportation.

The helicopter/aircraft is the private property of the gather contractor. Due to liability and safety concerns, Bureau policy prohibits observers from riding in or mounting cameras onto the aircraft. Should observers create unsafe flying and gathering conditions, for example, by hiring an aircraft to film or view a gather, the COR, in consultation with the gather contractor, will immediately cease gather operations.

The COR has the authority to stop the gather operation when the public engage in behavior that has the potential to result in harm or injury to the animals, employees, or other members of the public.

B. Planning for Public Observation at WH&B Gathers
During advance planning for public observation at WH&B gathers, the authorized officer should consult with the State External Affairs Chief or appropriate Public Affairs office. An internal communications plan will be developed for every gather (Attachment 2). It may also be helpful to prepare answers to frequently asked questions (Attachment 3).

C. Law Enforcement Plan
A separate Law Enforcement Plan should be developed if the need for law enforcement support is anticipated. The Law Enforcement Plan must be approved in advance by the Special Agent-In-Charge (SAC) or the State Staff Ranger of the State in which the gather is occurring.

D. Temporary Closure to Public Access
Under the authority of section 303(a) of the Federal Land Management and Policy Act (43 U.S.C. 1733(a)), 43 CFR 8360.0-7, and 43 CFR 8364.1, the authorized officer may temporarily close public lands within all or a portion of the proposed gather area to public access when necessary to protect the health and safety of the animals, the public, contractors and employees. Completion of a site-specific environmental analysis of the environmental impacts associated with the proposed closure and publication of a Federal Register Notice is required.

E. Gather Contract Pre-Work Conference
· Talk to the contractor about how many members of the public are expected and when. Discuss, and reach mutual agreement, about where best to position the public at the individual trap-sites to

allow the gather to be observed, while accomplishing the gather objectives and assuring the humane treatment of the animals and the safety of the BLM and contractor personnel, and public.
· No deviation from the selected viewing location(s) should be made, unless the gather operation is being adversely impacted. The COR will consult with the gather contractor prior to making any changes in the selected viewing locations.
· The BLM's policy prohibits it from ferrying observers in the helicopter or any other mode of conveyance unless an emergency situation exists. Review this policy with the contractor during the pre-work conference.

F. Radio Communication
· Assure there is effective radio communication between law enforcement personnel, gather COR or project inspectors (PIs), and other BLM staff.
· Identify the radio frequencies to be used.
· Communication with the gather contractor is through the BLM COR or PI, and from the gather contractor to the helicopter pilot. Direct communication between BLM personnel (other than the COR) and the helicopter pilot is not permitted, unless agreed upon by the BLM authorized officer and the contractor in advance, or the pilot is requesting information from the COR.

G. Pre- and Post-Action Gather Briefings
· Pre-briefings conducted by knowledgeable and experienced BLM staff can be helpful to the public.
· The pre-gather briefing is an opportunity to explain what individuals will see, why the BLM is conducting the gather, how the animals will be handled, etc.
· Post-action briefings may also be helpful in interpreting and explaining what individuals saw, what happened, why certain actions were taken, etc.

H. Summary of Individual Roles and Responsibilities
1. District and/or Field Office Managers
DMs and/or FMs are responsible for keeping the State Director and State WH&B Lead fully informed about the gather operation. Included is working with State/local public affairs staff to prepare early alerts if needed. An additional responsibility is determining if a law enforcement presence is needed.
2. Public Affairs Staff
The local district/field office public affairs staff is responsible for working with the COR, DM/FM, other appropriate staff, the State WH&B Program Lead, and the State Office of Communications to implement the communications strategy regarding the gather.
3. Law Enforcement
Develop and execute the law enforcement plan in consultation with District/Field Office Managers, the COR/PI, and the State's Special Agent-In-Charge or State Staff Ranger.
4. Contracting Officer's Representative (COR)/Project Inspectors (PIs)
The COR and the PI's primary responsibility is to administer the contract and manage the gather. A key element of this responsibility is to assure the safe and humane handling of WH&B. The COR is also responsible for working closely with the DM/FM and Public Affairs Staff to develop the communication plan, and for maintaining a line of communication with State, District, and Field Office managers, staff and specialists on the progress of, and any issues related to, the gather operation.

Timeframe: This instruction memorandum is effective immediately.

Budget Impact: Higher labor costs will be incurred while accommodating increased interest from the public to attend gather events. The budget impacts of unanticipated situations which can occur during WH&B gathers include substantial unplanned overtime and per diem expense. Through advance planning, necessary support staff can be identified (e.g., law enforcement, public affairs, or other BLM staff) and the cost-effectiveness of various options for providing staff support can be evaluated. In situations where public interest in a gather operation is greater than anticipated, the affected state should coordinate with the national program office and headquarters for assistance with personnel and funding.

Background: Heightened interest from the public to observe WH&B gathers has occurred. Advance planning for public observation of gather operations can minimize the potential for unanticipated situations to occur during WH&B gathers and assure the safety of the animals, the BLM and contractor personnel, and the public.

Manual/Handbook Sections Affected: No change or affect to the BLM manuals or handbooks is required.

Coordination: This IM was coordinated among WO-200 and WO-260 staff, State WH&B Program Leads, field WH&B Specialists, public affairs, and law enforcement staff in the field.

Contact: Questions concerning this policy should be directed to Susie Stokke in the Washington Office at (202) 912-7262 or Lili Thomas in the National Program Office at (775) 861-6457.

Appendix G: Federal Aviation Administration

General Operating and Flight Rules Sec. 91.119

Part 91 GENERAL OPERATING AND FLIGHT RULES
Subpart B--Flight Rules General
Sec. 91.119
Minimum safe altitudes: General.

Except when necessary for takeoff or landing, no person may operate an aircraft below the following altitudes:
(a) Anywhere. An altitude allowing, if a power unit fails, an emergency landing without undue hazard to persons or property on the surface.

(b) Over congested areas. Over any congested area of a city, town, or settlement, or over any open air assembly of persons, an altitude of 1,000 feet above the highest obstacle within a horizontal radius of 2,000 feet of the aircraft.

(c) Over other than congested areas. An altitude of 500 feet above the surface, except over open water or sparsely populated areas. In those cases, the aircraft may not be operated closer than 500 feet to any person, vessel, vehicle, or structure.

(d) Helicopters, powered parachutes, and weight-shift-control aircraft. If the operation is conducted without hazard to persons or property on the surface—

(1) A helicopter may be operated at less than the minimums prescribed in paragraph (b) or (c) of this section, provided each person operating the helicopter complies with any routes or altitudes specifically prescribed for helicopters by the FAA; and

(2) A powered parachute or weight-shift-control aircraft may be operated at less than the minimums prescribed in paragraph (c) of this section.]
Amdt. 91-311, Eff. 4/2/10

Appendix H. Water Quality and Macroinvertebrate Data

The inventory of streams pursuant to section 305(b) of the CWA (Clean Water Act 33 USC §1251 et seq. 1972) is accomplished using quantitative criteria set forth in the IDWQS (Idaho Water Quality Standards, Idaho Code 58.01.02) and the Idaho Small Stream Ecological Assessment Framework (IDEQ, 2002). The assessments typically involve collection of habitat data, macroinvertebrate samples and an electro-fish sample. These data are then in turn used to derive stream habitat (SHI), macroinvertebrate (SMI) and fish (SFI) indexes, these indexes are then used to calculate a 1 – 3 score based upon bioregion with 3 being the highest score, the specific criteria is given in Table 27 below. The scores for each index are then averaged. A stream with an average score greater than or equal to two is considered fully functioning. Due to the large scope of assessing all of the water bodies of the state the IDEQ (Idaho Department of Water Quality) have divided these bodies into lumped assessment units. Many of these assessment units have multiple monitoring, if any of the assessment sites do not meet the criteria for being fully functioning the entire assessment unit is considered impaired and consequently 303(d) listed.

Table 27. Index Scoring Criteria Based upon Bioregion

	Bioregion Classification			
Condition Category	**Northern Mountains**	**Central and Southern Mountains**	**Basins**	**Condition Rating**
SMI Bioregion Scoring Criteria				
Above the 25th percentile of reference condition	≥65	≥59	≥51	3
10th to 25th percentile of reference condition	57-64	51-58	43-50	2
Minimum to 10th percentile of reference condition	39-56	33-50	33-42	1
Below minimum of reference condition	<39	<33	<33	Minimum Threshold
SFI Bioregion Scoring Criteria				
	Rangeland	Forest		
Above the median of reference condition	≥82	≥81		3
25th percentile to median of reference condition	62-81	67-80		2

Table 27. Index Scoring Criteria Based upon Bioregion				
	Bioregion Classification			
	Northern Mountains	**Central and Southern Mountains**	**Basins**	**Condition Rating**
5th to 25th percentile of reference condition	39-61	34-66		1
Below 5th percentile of reference condition	<39	<34		Minimum Threshold
SHI Bioregion Scoring Criteria				
	Northern Rockies	Northern Basin and Range	Snake River Basin/ High Desert	
Above 25th percentile of reference condition	≥66	≥63	≥58	3
10th to 25th percentile of reference condition	58-65	50-62	55-57	2
below 10th percentile of reference condition	<58	<50	<55	1

Table 31 summarizes multiple metrics from fixed-area quantitative aquatic benthic macroinvertebrate sampling conducted by the BLM Challis Field Office within the CHMA. Sample processing, organism identification, method development, and calculation of metrics conducted by the National Aquatic Monitoring Center, Utah State University, Logan, UT (NAMC, 2009). * = Site is located outside of the CHMA, but within the cumulative analysis area. The stream and location where sample reach occurred are presented with associated metrics: *Richness = an estimate of community structure and stream health based on the number of distinct taxa; # of Families = Similar to richness it is the number of taxanomic groups (families) present in the sample; # of EPT Taxa = the number of distinct taxa within the insect Orders Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddis flies) commonly considered sensitive to pollution; # of Intolerant Taxa & # of Tolerant Taxa= The Hilsenhoff Biotic Index [(HBI) (Hillsenhoff 1987)] summarizes the overall pollution tolerances of the taxa collected, and has been used to detect nutrient enrichment, high sediment loads, low dissolved oxygen, and thermal impacts. Taxon HBI values can also be used to determine the number of pollution intolerant and tolerant taxa occurring at a site, where taxa with HBI values < 2 were considered intolerant clean water taxa and taxa with HBI values > 8 were considered pollution tolerant taxa; # of Clinger Taxa = The number of taxa characterized as those which generally cling to the tops of rocks and can be reduced by sedimentation or abundant algal growths.*

Appendix I Annual Indicator Monitoring

2001

Horse Basin grazing AUM Total - 475 from 7/16 – 8/7

- 7/23/2001 – 232 Horses Counted
- March 30, 2001 – Use along Horse Basin Creek was observed to have exceeded use standards. This was a pre livestock assessment
  July 12, 2001 HBC-KA1, 7.1" stubble height & HBC-KA2, 10.1" stubble height
  July 27, 2001 HBC-KA2, 7" stubble height
  Aug 15, 2001 HBC-KA1, 3.5" stubble height, 5% shearing- livestock use not apparent
  HBC-KA2, 5" stubble height, less than 5% shearing
  Oct 12, 2001 HBC-KA2, 2" stubble height
  Oct 16, 2001 HBC-KA1, 3" stubble height, less than 5% shears

2002

- Horse Basin Rested – 0 cattle AUMs
- 7/25/2002 – 251 horses Counted
- July 16, 2002 HBC-KA2, 8.5" Stubble Height

2003

- Horse Basin grazing AUM Total - 519 from 6/16 – 7/11
- 8/28/2003 – 203 horses counted
- June 17, 2003 LHB-KA1, 6" stubble height
- June 17, 2003 HBC-KA1, 12" stubble height
- June 17, 2003 HBC-KA2, 8" stubble height
- July 1, 2003 LHB-KA1, 4" stubble height
- July 1, 2003 HBC-KA2, 4" stubble height
- Oct. 23, 2003 LHB-KA1, 4" stubble height, 15% bank shears – horse use was apparent
- Oct. 23, 2003 HBC-KA2, 2" stubble height, 26% bank shears – exceedance of 3" stubble height and 5% bank shears attributed to wild horse use

2004

- Horse Basin grazing AUM Total - 609 from 6/21 – 7/12
- 6/28/2004 – 241 horses counted
- July 28, 2004 HBC-KA2, 4" stubble height
- Oct. 12, 2004 LHB-KA1, 3.5" stubble height, 19% shears – very little livestock sign; exceedance of 5% attributed to wild horse use
- Oct. 12, 2004 HBC-KA1, 12+" stubble height, 0% shears

2005

- Horse Basin grazing AUM Total - 383 from 7/16 – 8/11
- 9/29/2005 – 208 horses counted
- Aug. 31, 2005 HBC-KA2, 6" stubble height, slight use on willows
- Oct. 18, 2005 HBC-KA2, 3" stubble height, light to moderate use on willows

2006

- Horse Basin Rested – however cattle trailing occurred through this pasture
- 9/21/2006 – 231 horses counted
- June 21, 2006 HBC-KA2(Upstream)- 6" stubble height, alteration 3.6%, shearing <1%
- June 21, 2006 HBC-KA2(Downstream)- 5" stubble height, alteration 9.6%, shearing 5%
- Oct. 11, 2006 HBC-KA2 - 2" stubble height, 13.6% alteration, shearing <5%

2007

- Horse Basin grazing AUM Total - 618, from 6/16-7/13 use was focused in upper horse basin
- 9/2007 – 360 horses estimated
- July 17, 2007 HBC-KA2 – 4.1" stubble height, alteration 40%, slight use on willows
- Nov 20, 2007 HBC-KA2 – 2" stubble height, alteration not measured, slight use on willows

2008

- Horse Basin grazing AUM Total – 691, from 7/13-7/29
- 9/18/2008 – 413 horses counted

2009

- Horse Basin grazing AUM Total – 378, from 7/13 - 8/1
- 9/2009 224 - horses estimated
- 7/16/2009 HBC-KA2 – 5" stubble height, Alterations were 24% on right bank and 22.5% on left bank (measures taken prior to grazing indicating horse use)
- 9/11/2009 HBC-KA2 – 3.5" stubble height

2010

- Horse Basin Rested, 73 grazing AUMS attributed to trailing on 7/14-7/16
- 9/2010 263 - horses estimated
- 8/10/2010 HBC-KA1 – 12" plus stubble height, alterations not measured
- 11/03/2010 HBC-KA2 – 4.1" left bank & 3.1" right bank stubble height, 39% alterations

2011

- Horse Basin Grazing AUM Total – 606, 7/12 – 8/8
- 9/2011 275 - horses estimated
- 6/29/2011 HBC-KA1
- 6/29/2011 HBC-KA2
- 8/25/2011 HBC-KA1
- 8/25/2011 HBC-KA2
- 11/1/2011 HBC-KA1 – 5.3" stubble height, 12% alterations
- 11/1/2011 HBC-KA2 – 4.7" stubble height, 25% alterations
- 11/4/2011 LHB-KA1 – 3.9" stubble height, 31% alterations

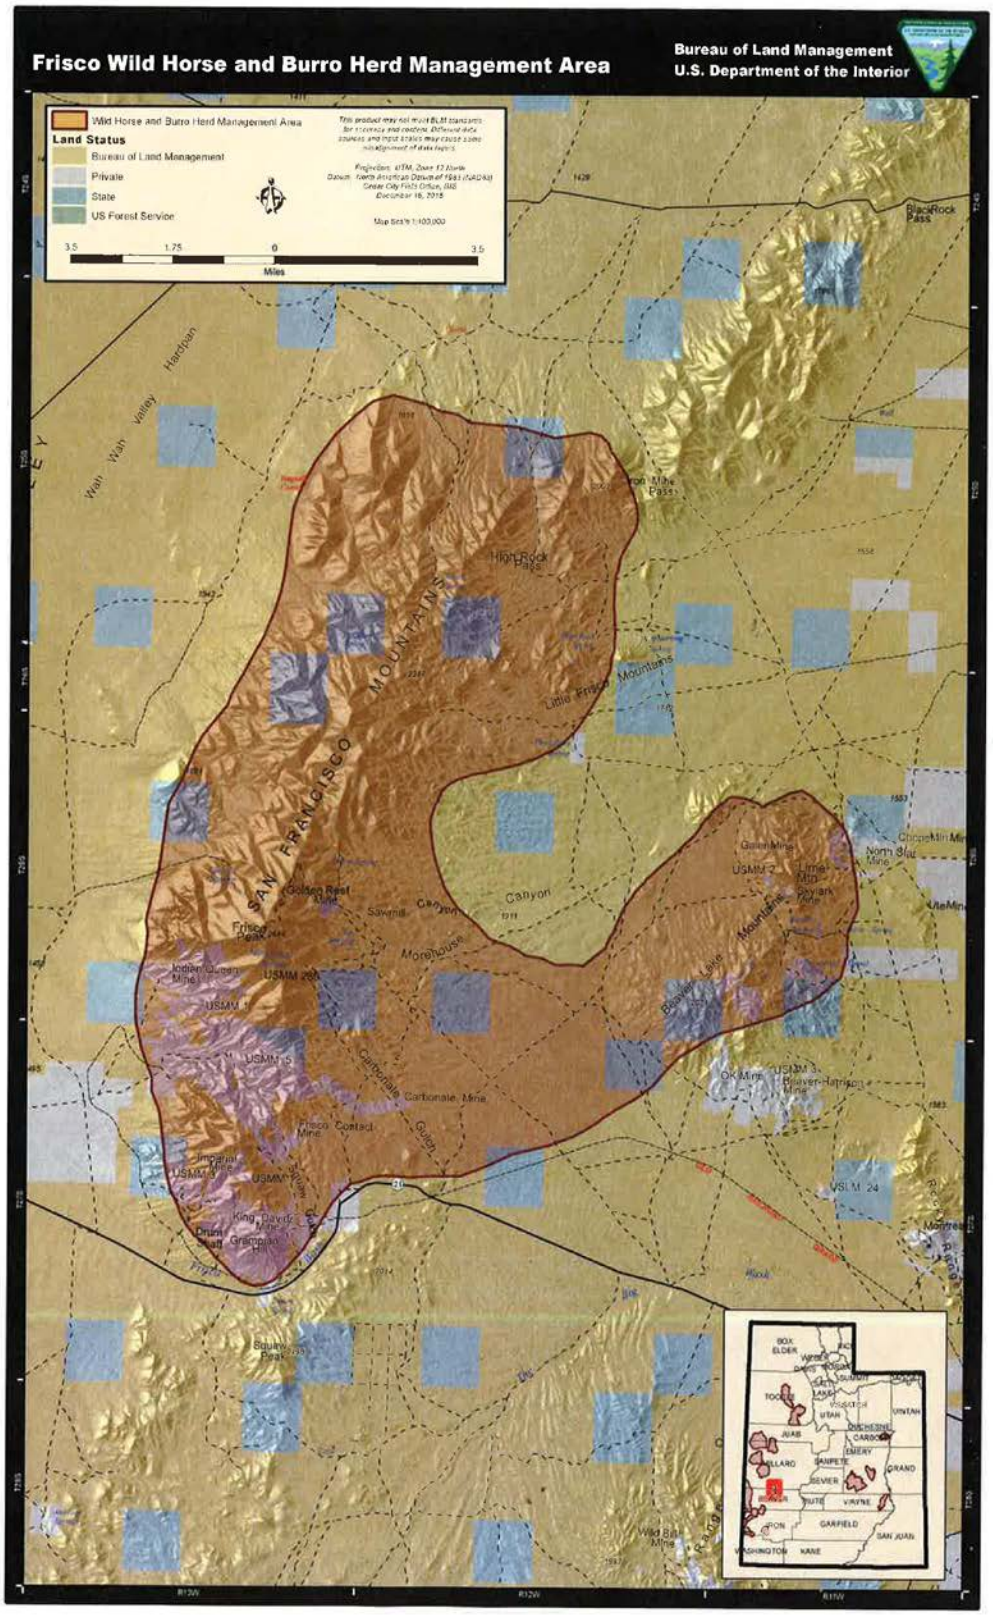
1.0 Purpose of and Need for the Proposed Action

1.1 Introduction

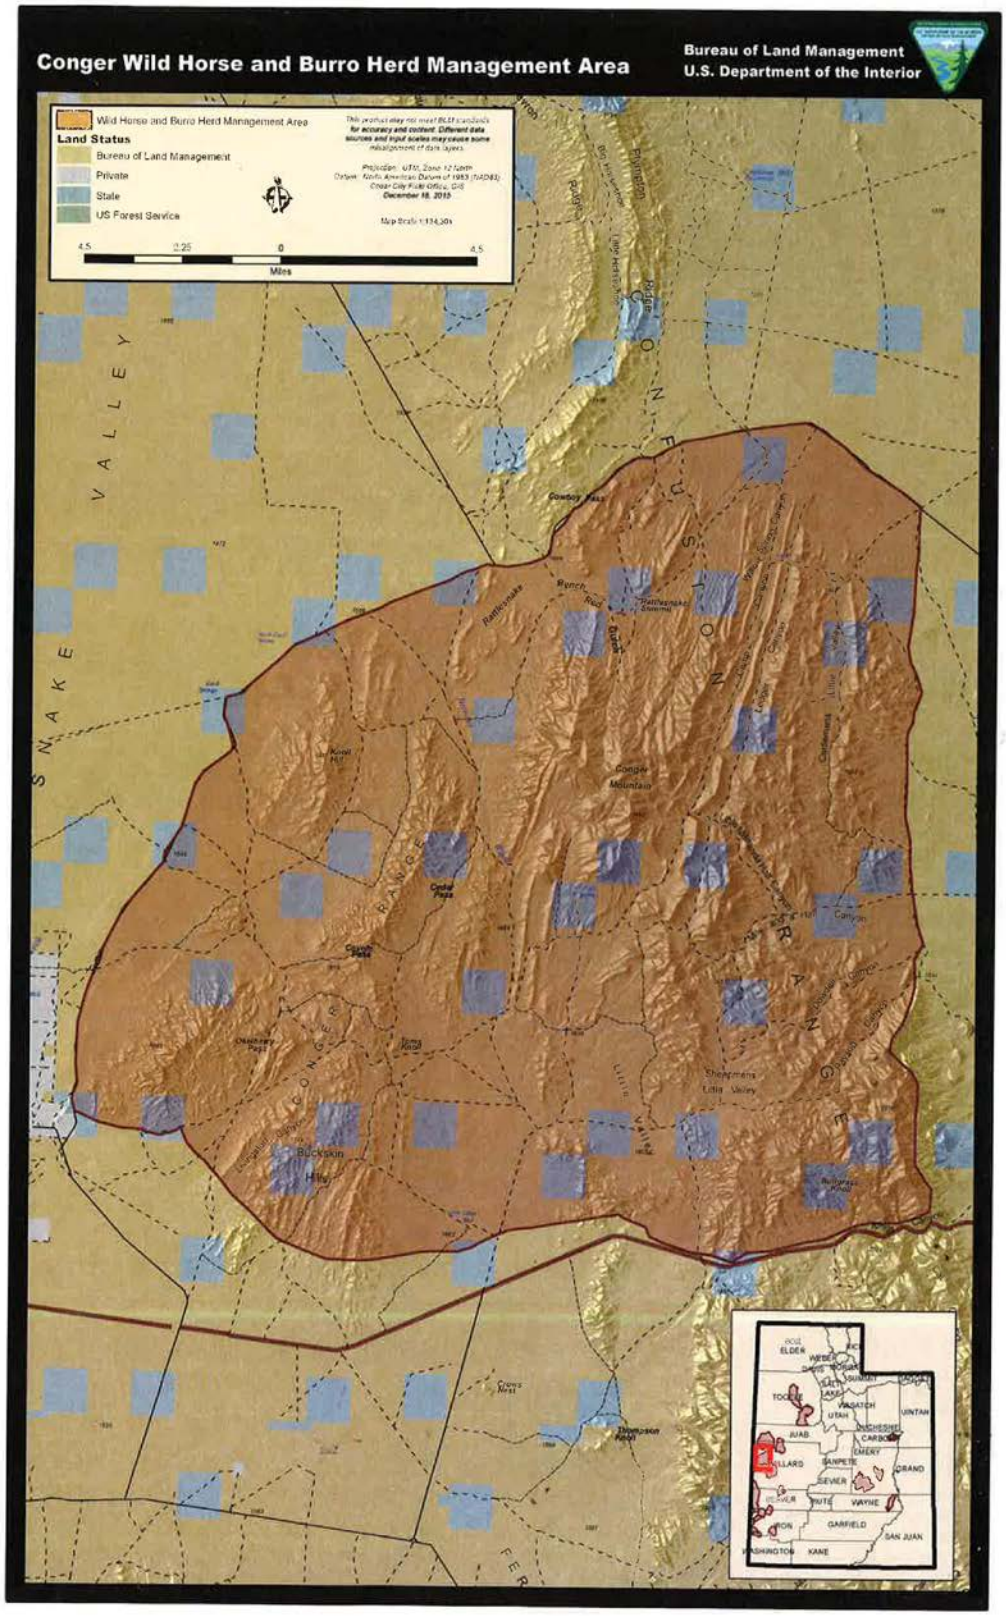
This Environmental Assessment (EA) has been prepared to disclose and analyze the environmental consequences of the Population Control Research Wild Horse Gather for the Conger and Frisco Herd Management Areas (HMAs) as proposed by the Bureau of Land Management's Fillmore and Cedar City field offices and in cooperation with United States Geological Survey (USGS) Fort Collins Science Center and Colorado State University (CSU). The EA is a site-specific analysis of potential impacts that could result in the implementation of a proposed action or alternatives to the proposed action. The EA assists the BLM in project planning and ensuring compliance with the National Environmental Policy Act (NEPA), and in making a determination as to whether any "significant" impacts could result from the analyzed actions. "Significance" is defined by NEPA and is found in regulation 40 CFR 1508.27. An EA provides evidence for determining whether to prepare an Environmental Impact Statement (EIS) or a statement of "Finding of No Significant Impact" (FONSI). If the decision maker determines that this project has "significant" impacts following the analysis in the EA, then an EIS would be prepared for the project. If not, a Decision Record may be signed for the EA approving the selected alternative, whether the proposed action or another alternative. A Decision Record (DR), including a FONSI statement, documents the reasons why implementation of the selected alternative would not result in "significant" environmental impacts (effects) beyond those already addressed in the Warm Springs Resource Area Proposed Resource Management Plan and Final Environmental Impact Statement (RMP/EIS), 1986 and Pinyon Management Framework Plan/Final EIS, 1983.

1.2 Background



Since the passage of the Wild Free-Roaming Horses and Burros Act (WFRHBA) of 1971, BLM has refined its understanding of how to manage wild horse population levels. By law, BLM is required to control any overpopulation, by removing excess animals, once a determination has been made that excess animals are present and removal is necessary. Program goals have always been to establish and maintain a "thriving natural ecological balance," which requires identifying the Appropriate Management Level (AML) for individual herds. In the past two decades, goals have also explicitly included conducting gathers and applying contraceptive treatments to achieve and maintain wild horse populations within the established AML, so as to manage for healthy wild horse populations and healthy rangelands. Management actions resulting from shifting the program emphasis include the use of fertility control, and adjusting sex ratios. Both of these management actions can reduce total population growth rates in the short term, and increase gather intervals. Other efforts include improving the accuracy of population inventories and collecting genetic baseline data to support genetic health assessments. Decreasing the numbers of excess wild horses removed while also reducing population growth rates and ensuring the welfare of wild horses on the range are all consistent with findings and recommendations from the National Academy of Sciences (NAS), American Horse Protection Association (AHPA), the American Association of Equine Practitioners (AAEP), Humane Society of the United States (HSUS), Government Accountability Office (GAO), Office of Inspector General (OIG) and current BLM policy. BLM's management of wild horses must also

be consistent with Standards and Guidelines for Rangeland Health and for Healthy Wild Horse Populations developed by the Northeastern Great Basin Resource Advisory Council (RAC).



The current estimated population of wild horses in the Frisco HMA (Map A) is 288 (see Appendix I). This number is based on the Utah BLM's population statistics (2/28/2016) compiled from the most recent aerial survey of the HMA that took place in February 2016. The current population is about 4 times over the AML upper limit. It was last gathered in December of 2012.

The current estimated population of wild horses in the Conger HMA (Map B) is 310 (see Appendix I). This number is based on the Utah BLM's population statistics (2/28/2016) compiled from the most recent aerial survey of the HMA that took place in February 2016. The current population is about 4 times over the AML upper limit. It was last gathered in September 2010. Since the passage of the WFRHBA, management knowledge regarding horse population levels has increased. For example, wild horses are capable of increasing numbers 15-20% annually (NAS 2013), resulting in the doubling of wild horse populations about every 3 years.

1.3 Need for the Proposed Action

This action is needed to achieve population sizes that would provide an appropriate sample size of study animals for both the treated and control populations for statistical analysis; remove wild horses from areas not designated for wild horse use; slow population growth rates; remove excess wild horses from within the HMA; protect rangeland resources from deterioration associated with an overpopulation of wild horses; achieve population sizes that are consistent with the established AMLs; and restore and maintain a thriving natural ecological balance and multiple use relationship on the public lands consistent with the provisions of Section 3(b) (2) of the WFRHBA. Furthermore, the action is needed to ensure current and future populations of healthy wild horses.[1]

1.4 Purpose of the Proposed Action

The purpose of the Proposed Action is to remove excess wild horses within the Conger Mountain and Frisco HMAs to bring the populations of both HMAs towards AML, while achieving a population of approximately 100 animals in first year on each HMA for the purpose of gathering data for USGS and CSU studies. The population size has been identified appropriate for a comparative statistical analysis for the proposed studies by USGS and CSU that would measure core demographic parameters. Any wild horses located outside the HMAs (in areas not designated for their use) would also be removed. In addition, the USGS research project would provide empirical data for population and ecosystem modeling, to improve future management of wild horses, and to contribute to a better understanding of the behaviors and ecology of wild horses. The behavioral studies at Conger HMA (treatment population) would inform BLM about the behavioral effects of gelding a portion of a wild horse herd. That type of information is not currently available. Studies at both Conger HMA and Frisco HMA would improve BLM's understanding of wild horse demography. The NAS committee recommended the use of statistical models for the understanding of herd demography, but little empirical data exists on which to build such models. The data collected from the studies would contribute to population dynamics models that may point to environmental factors that have the greatest influence on demographic parameters. The data would also be used to improve, update, and revise the WinEquus population model currently being used by BLM wild horse specialists. Following the completion of the research study, additional gathers in both HMAs would be necessary to remove excess wild horses to achieve a thriving ecological balance with multiple resources by achieving and maintain AMLs within the HMAs. Some gelded animals would remain on the Conger HMA as a non-reproductive segment of the population for further observation and to achieve management objectives.

---

1 The Interior Board of Land Appeals (IBLA) defined the goal for managing wild horse (or burro) populations in a thriving natural ecological balance as follows: "As the court stated in Dahl vs. Clark, supra at 594, the 'benchmark test' for determining the suitable number of wild horses on the public range is 'thriving natural ecological balance.' In the words of the conference committee which adopted this standard: 'The goal of WH&B management should be to maintain a thriving ecological balance (TNEB) between WH&B populations, wildlife, livestock and vegetation, and to protect the range from the deterioration associated with overpopulation of wild horses and burros.'"

1.5 Land Use Plan Conformance

The action alternatives are subject to the:

- ❒ Warm Springs Resource Area Resource Management Plan/Record of Decision Rangeland Program Summary (RMP/ROD), 1987.
- ❒ Pinyon Management Framework Plan/Final EIS, 1983.
- ❒ Frisco Herd Management Area Plan (HMAP), 2012.

The Pinyon MFP (RM 1.8, WH1.1…) states, "…remove horses as required to maintain horse numbers at or below 1982 inventory levels…". The MFP also states that the number of herd units and the population of each herd would depend on the results of monitoring studies, range condition, viewing opportunities, cooperative management, and range developments.

The Warm Springs Resource Area RMP states, "Horse numbers in the Conger Mountain…will be maintained near the following allocation levels. Horse numbers will be kept between 80 and 40 head in the Conger HMA…". The RMP also states that this will require periodic removals and that vegetation monitoring will be used to determine if management objectives are being met.

The Frisco HMAP states, "The current Appropriate Management Level (AML) for the area is 60 horses with not less than 30." This plans monitoring objectives includes monitoring; use of vegetation and waters by wild horses; individual and herd behavior; individual and herd health; movements of identified wild horses to determine use patterns and seasonal migrations and range of travel.

1.6 Relationship to Laws, Regulations, and Other Plans

The action alternatives are in conformance with the WFRHBA (as amended), applicable regulations at 43 CFR § 4700 and BLM policies. Included are:

❒ 43 CFR 4710.3-1 Herd Management Areas.
Herd management areas shall be established for the maintenance of wild horse and burro herds. In delineating each herd management area, the authorized officer shall consider the appropriate management level for the herd, the habitat requirements of the animals, the relationships with other uses of the public and adjacent private lands, and the constraints contained in 4710.4. The authorized officer shall prepare a herd management area plan, which may cover one or more herd management areas.

❒ 43 CFR 4710.4 Constraints on Management.
Management of wild horses and burros shall be undertaken with limiting the animals' distribution to herd areas. Management shall be at the minimum feasible level necessary to attain the objectives identified in approved land use plans and herd management area plans.

❒ 43 CFR 4720.1 Removal of excess animals from public lands.
Upon examination of current information and a determination by the authorized officer that an

excess of wild horses or burros exists, the authorized officer shall remove the excess animals immediately.

❒ 43 CFR 4740.1 Use of motor vehicles or aircraft.

(a) Motor vehicles and aircraft may be used by the authorized officer in all phases of the administration of the Act, except that no motor vehicle or aircraft, other than helicopters, shall be used for the purpose of herding or chasing wild horses or burros for capture or destruction. All such use shall be conducted in a humane manner.

(b) Before using helicopters or motor vehicles in the management of wild horses or burros, the authorized officer shall conduct a public hearing in the area where such use is to be made.

❒ All supplemental authorizations contained in Appendix 1 of the National NEPA Handbook 1790-1.

1.7 Scoping and Identification of Issues

Consultation and coordination with BLM, the Utah State Historic Preservation Office (SHPO), the Utah Division of Wildlife Resources (UDWR), US Fish & Wildlife Service (USFWS), Native American Indian tribes and routine business contacts with livestock operators and others, has underscored the need for the BLM to maintain wild horse and burro populations within the AML.

The Proposed Action was posted on the Electronic Notification Bulletin Board (ENBB) September 24, 2015 for public notification and then posted on the BLM's ePlanning site November 13, 2015. Responses were received from Utah's Public Lands Policy Coordinating Office and American Wild Horse Preservation Campaign.

The following issues were identified as a result of consultation/coordination and internal scoping relative to the BLM's management of wild horses in the planning area:

1. Impacts to individual wild horses and the herd. Measurement indicators for this issue include:
    - Expected impacts to individual wild horses from handling stress
    - Expected impacts to herd social structure
    - Expected effectiveness of proposed fertility control application
    - Potential effects to genetic diversity
    - Potential impacts to animal health and condition

2. A need to implement different or additional population control methods in order to maintain population size within AML over the long-term. Measurement indicators for the issue include:
    - Projected population size and annual growth rate (WinEquus population modeling)
    - Projected gather frequency
    - Projected number of excess animals to be removed and placed in the adoption, sale, and short and long-term holding pipelines over the next 10 years

3. Impacts to Rangeland Heath Standards/livestock grazing. Measurement indicators for this issue include:

- Expected forage utilization and potential competition for forage and water over time
- Potential impacts to Rangeland Health Standards/vegetation and resources

Impacts could also be expected to wildlife and safety. Other resources which were considered are described in Appendix E.

2.0 Proposed Action and Alternatives

2.1 Introduction

This section of the EA describes the Proposed Action and alternatives, including any that were considered but eliminated from detailed analysis. Three alternatives are considered in detail:

- **Alternative 1** Frisco HMA: **Proposed Action** – Capture wild horses in order to remove excess animals above the target research control population of 100 wild horses and establish a 50% male to female sex ratio and all age classes. A 5 year research study would be implemented. Target population would be above high AML. Following the completion of the research study, 2 to 3 additional gathers would be necessary to remove excess wild horses to achieve and maintain AML over the 10 year life of this document.
- **Alternative 1** Conger Mountain HMA: **Proposed Action** – Capture wild horses in order to remove excess animals above the target research treatment population of 100 and establish a 50% male to female sex ratio and all age classes. A 5 year research study would be implemented. A portion of the male population (up to 75%) would be treated (gelded) during a subsequent gather in Year 2 to evaluate the effects of maintaining a population of gelded males on the behavior and spatial ecology of the overall population, and to determine their health and short-term survival. Target population would be above high AML. Following the completion of the research study, 2 to 3 additional gathers would be necessary to remove excess wild horses to achieve and maintain AML over the 10 year life of this document.
- **Alternative 2** Conger and Frisco HMAs: **Removal Only** – Capture and remove excess animals to achieve and maintain AML. No research study would be implemented.
- **Alternative 3** Conger and Frisco HMAs: **No Action** — Defer gather, removal and research on these HMAs.

The Proposed Action and Alternative 2 were developed to respond to the identified resource issues and the Purpose and Need to differing degrees. The No Action Alternative would not achieve the identified Purpose and Need. However, it is analyzed in this EA to provide a basis for comparison with the other action alternatives, and to assess the effects of not conducting a gather at this time. The No Action Alternative is in violation of the WFRHBA which requires the BLM to immediately remove excess wild horses.

2.2 Description of Alternatives Considered in Detail

2.2.1 Alternative 1 -Proposed Action

Frisco HMA

The Proposed Action would reduce the population of wild horses on the Frisco HMA to 100 head by gather approximately 250 and removing approximately 175 head of excess wild horses from within and outside the HMA beginning on or about July 1, 2016. All adults would be freeze marked with a unique 4-digit hip mark to facilitate individual identification and monitoring. Population aerial inventories would be conducted prior to and after the gather and removal. Animals would be removed using a selective removal strategy that would allow for

success within the research study parameters without compromising the established herd dynamics. Approximately 75 of the captured wild horses would be released with an objective of establishing a 50%/50% male/female sex ratio and meeting the desired research population objective of 100 animals. Radio/GPS tags would be braided into their tails or manes on 20 adult males and radio/GPS collars or tags would be placed on 40 adult females and up to 15 yearling females (Year 1 of research study). Once tags are braided into the tails or manes they would be held in place with a non-toxic, low temperature curing epoxy resin. Mares collared for the multiple year study would be 3 years old or older. All mares being collared would be in Henneke body condition score 4 or greater. Animals that are "thin" (Henneke score of <3), deformed, or who have any apparent neck problems wouldn't be fitted with a collar. As tags are small (<200g) and are not worn around the neck they are considered of low burden to the animal, and therefore could potentially be worn by animals in lower boy condition. All collars would be fitted according to procedures outlined in Appendix H. All radio collars would have a manual release mechanism that can be remotely activated in case of emergency and a timed release mechanism which would be programmed to release at the end of the study period. No collars would remain on wild horses indefinitely. If the collar drop-off mechanism fails at the end of the study those individual horses would be captured and the collars manually removed. Each collared horse would be observed once a month while collared. Every effort would be made to release horses to the same general area from which they were gathered. Dependent foals would be released with their mare. Radio marked females would be monitored to check for foals. Foals and radio marked animals would be monitored through summer 2017 and data would additionally be recorded related to survival rates, movement rates, and spatial ecology. Global positioning system (GPS) and very high frequency (VHF) radio collars and tags can be used to provide high spatial and temporal resolution information for detecting free-roaming horse movement, locations and for other research purposes including but not limited to effectiveness of population inventories and demographics.

Year 2 (Oct 2017-Sept 2018)
Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month throughout the year to check individuals wearing collars. In the fall of 2017, collect fecal samples of radio marked mares to determine pregnancy; collect non-invasive fecal samples from foals to determine paternity in order to inform individual male reproductive success. In winter 2017/2018, conduct an aerial inventory to assess population size. In spring and summer 2018, monitor radio marked females to check for foals, and monitor foals and radio marked adults through the summer for survival, movement rates, and spatial ecology.

Year 3 (Oct 2018-Sept 2019)
Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month throughout the year to check individuals wearing collars. In the fall of 2018, collect fecal samples of radio marked mares to determine pregnancy; collect fecal samples from foals to determine paternity for male reproductive success analyses. In winter 2018/2019, conduct an aerial inventory to assess population size. In spring and summer 2019, monitor radio marked females to check for foals and monitor foals and radio marked adults throughout summer for survival, movement rates, and spatial ecology.

Year 4 (Oct 2019-Sept 2020)
Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month throughout the year to check individuals wearing collars. In the fall of 2019, collect fecal samples of radio marked mares to determine pregnancy; collect fecal samples from foals to determine paternity for male reproductive success analyses. In winter 2019/2020, conduct an aerial inventory to assess population size. In spring and summer 2020, monitor radio marked females to check for foals and monitor foals and radio marked adults through the summer for survival, movement rates, and spatial ecology.

Year 5 (Oct 2020-Sept 2021)
Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month throughout the year to check individuals wearing collars. In the fall of 2020, collect fecal samples of radio marked mares to determine pregnancy; collect fecal samples from foals to determine paternity. In winter 2020/2021, conduct an aerial inventory to assess population size. In spring and summer 2021, monitor radio marked females to check for foals and monitor foals and radio marked adults through the summer for survival and movements, and to check that radio collars drop off as programmed. The data would begin to be analyzed, population models would be developed, and results written up and submitted to peer-reviewed journals.

Year 6-10 (Oct 2021 – Sept 2026)
Upon the conclusion of the research study the BLM would conduct gathers to remove excess wild horses to achieve a thriving ecological balance with multiple resources by achieving and maintain AML. Gathers and management of the Frisco HMA would be in accordance with the Frisco HMAP where the sex ratio would be returned to a 60/40 male to female ratio pending study results. Study results would be used in future management objectives and incorporated in the Frisco HMAP. Several gathers may be necessary to achieve and maintain AML based on National holding space availability and National gather priorities.

Conger Mountain HMA
The Proposed Action would gather up to 300 and remove approximately 225 excess wild horses from within and outside the Conger Mountain Herd Management Area (HMA) beginning on or about July 1, 2016. All adults would be freeze marked with a unique 4-digit hip mark to facilitate individual identification and monitoring. Population aerial inventories would be conducted prior to and after the gather and removal. Animals would be removed using a selective removal strategy that would allow for success in achieving the necessary population parameters for the research study, without compromising the established herd dynamics. Approximately 75 of the captured wild horses would be released with an objective of establishing a 50%/50% male/female sex ratio and meeting the desired research population objective of 100 animals. At the beginning of the study, Year 1, 30 mature (≥3 years old) males would be marked with radio tags braided into their tails or manes held in place with a non-toxic, low temperature curing epoxy resin, and 30 mares would be radio collared. Mares collared for the multiple year study would be 3 years old or older. All mares being collared would be in Henneke body condition score 4 or greater. Animals that are "thin" (Henneke score of <3), deformed, or who have any apparent neck problems wouldn't be fitted with a collar. As tags are small (<200g) and are not worn around the neck they are considered of low burden to the animal, and therefore could potentially be worn by animals in lower boy condition. All collars would be fitted according to

procedures outlined in Appendix H. All radio collars would have a manual release mechanism that can be remotely activated in case of emergency and a timed release mechanism which would be programmed to release at the end of the study period. No collars would remain on wild horses indefinitely. If the collar drop-off mechanism fails at the end of the study those individual horses would be captured and the collars manually removed. Each collared horse would be observed once a month while collared. Every effort would be made to release horses to the same general area from which they were gathered. Dependent foals would be released with their mare. Radio collared mares would be observed 1-2x/month over winter to check radio collars. In the spring and summer 2017, radio marked females would be monitored to check for foals and data would be recorded on all radio marked individuals related to survival rates, movement rates and spatial ecology. We would collect fecal samples of radio marked mares to determine pregnancy and collect fecal samples from foals to determine paternity for male reproductive success analyses. Pre-treatment behavioral data would be collected on 16 tagged males (harem stallions and bachelors) and 4 collared females, plus their social associates, between March and September 2017.

Year 2 (Oct 2017-Sept 2018)
In fall 2017 conduct a gather of all males and their groups. Based on consultation with BLM specialists, 50% to 75% of all adult males in the population would be gelded. This would be approximately 37 males, which would be randomly selected for treatment (gelding), other males would not be treated and would serve as control animals. All captured horses (males and females, plus juveniles and foals) would be brought to the Delta Wild Horse Facility. The gelding of the selected males would be conducted there by a veterinarian in a controlled environment, and those treated animals would be provided sufficient time to heal and be monitored for complications. Both treated and untreated males would be released back to the HMA along with females in the population at approximately the same time. Of the radio-tagged males, 8 treatment and 8 control males (plus 4 collared mares) would continue as focal study animals for intensive behavioral data collection. This would consist of over 1000 hours of behavioral observations collected between March and September each year of the research study. The remaining radio-marked individuals would be monitored less frequently, in order to record data related to survival rates, movement rates, fertility and fecundity and spatial ecology. We would collect fecal samples of radio marked mares to determine pregnancy and collect fecal samples from foals to determine paternity for male reproductive success analyses.

Year 3 (Oct 2018-Sept 2019)
In winter 2018/2019, conduct an aerial inventory to assess population size. Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month throughout the year to check individuals wearing collars. Record post-treatment data on behavioral variables during March to September. Researchers would collect fecal samples of radio marked mares to determine pregnancy and collect fecal samples from foals to determine paternity for male reproductive success analyses, and record survival, presence of foals, and other population parameters.

Year 4 (Oct 2019-Sep 2020)
In winter 2019/2020, conduct an aerial inventory to assess population size. Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month

throughout the year to check individuals wearing collars. Record post-treatment data on behavioral variables during March to September. Researchers would collect fecal samples of radio marked mares to determine pregnancy and collect fecal samples from foals to determine paternity for male reproductive success analyses, and record survival, presence of foals, and other population parameters.

Year 5 (Oct 2020-Sep 2021)
In winter 2020/2021, conduct an aerial inventory to assess population size. Continue gathering data with the use of radio collars and tags, locating individuals approximately 1-2x/month throughout the year to check individuals wearing collars. Record final year of post-treatment data on behavioral variables during March to September. Researchers would collect fecal samples of radio marked mares to determine pregnancy and collect fecal samples from foals to determine paternity for male reproductive success analyses, and record survival, presence of foals, and other population parameters, and to check that radio collars drop off as programmed. The data would begin to be analyzed, and results written up and submitted to peer-reviewed journals.

Year 6-10 (Oct 2020 – Sept 2025)
Upon the conclusion of the research study the BLM would conduct gathers to remove excess wild horses to achieve a thriving ecological balance with multiple resources by achieving and maintain AML. Gathers and management of the Conger HMA would be in accordance to Warm Springs Resource Area RMP and recent management practices where the sex ratio would be adjusted to favor males (60/40 male to female ratio) pending research results. Several gathers may be necessary to achieve and maintain AML based on National holding space availability and National gather priorities. During the gathers, any gelding from the research study that is captured would be evaluated for return based on the health of the individual and management objectives.

Description of Gelding Procedure
Stallions between 5 and 20 years of age and with a Henneke body condition score of 3 or higher (Henneke 1983) would be randomly selected for gelding. No animals which appear to be distressed, injured, or in poor health or condition would be selected for gelding. Stallions would not be gelded within 72 hours of capture. The surgery would be performed at a BLM-managed holding center by a veterinarian using general anesthesia and appropriate surgical techniques (see Colorado State University Institutional Animal Care and Use Committee protocol Appendix A and Gelding SOPs in Appendix C). The final determination of which specific animals would be gelded would be based on the professional opinion of the attending veterinarian in consultation with the Authorized Officer.

The animal would be sedated with Xylazine at 1.1mg/kg administered intravenously followed 2-3 minutes later with Ketamine to induce anesthesia. The Ketamine is given at a dose of 2.2mg/kg intravenously. They are placed in lateral recumbency and the surgical site is prepped using a Chlorhexidine scrub. The surgeon would wear sterile gloves. The scrotum is incised over the testicles and the testicles are removed using a Henderson castrating tool. The incision is left open to drain. Each stud would be given a Tetanus shot, also an intramuscular injection of Procaine Penicllin G at a rate of 22,000 units/kg and an intravenous injection of Flunixin Meglumine at 2.2mg/kg.

Any males that have an inguinal or scrotal hernias would be removed from the population, sent to a regular BLM facility and be treated surgically as indicated if possible or euthanized if they have a poor prognosis for recovery according to BLM policy (IM 2009-041, IM 2009-063). Horses with only one descended testicle may be removed from the population and managed at a regular BLM facility according to BLM policy or anesthetized with the intent to locate the undescended testicle for castration. If an undescended testicle cannot be located, the animal may be recovered and removed from the population if no surgical exploration has started. Once surgical exploration has started those that cannot be completely castrated would be euthanized prior to recovering them from anesthesia according to BLM policy. All animals would be rechecked by a veterinarian the day following surgery. Those that have excessive swelling, are reluctant to move or show signs of any other complications would be held in captivity and treated accordingly as they normally would in a BLM facility. Once released to the wild no further veterinary interventions are possible.

Selected stallions would be shipped to the facility, gelded, and returned to the range within 30 days. Gelded animals would be monitored periodically for complications for approximately 7-10 days following release. This monitoring may be completed either through aerial recon if available or field observations from major roads and trails. The goal of this monitoring is to detect complications if they are occurring and determine if the horses are freely moving about the HMA. All adults would have been freeze-marked at the first gather with a 4 digit freezemark number high on their hip to facilitate post-treatment and routine field monitoring. Post-gather monitoring would be used to document whether or not geldings form bachelor bands or intermix with the breeding population as expected. Other periodic observations of the long term outcomes of gelding would be recorded during routine resource monitoring work. Such observations would include but not be limited to band size, social interactions with other geldings and harem bands, distribution within their habitat, forage utilization and activities around key water sources. More intensive observations of gelded and non-gelded wild horses would be conducted by a CSU/USGS research team. Periodic population inventories and future gather statistics would assist BLM to determine if managing a portion of the herd as non-breeding animals is an effective approach to slowing the annual population growth rate by replacing breeding mares with sterilized animals, and thereby extending the gather cycle when used in conjunction with other population control techniques.

It should be noted that adequate reduction of female horse fertility rates is expected to result only if a large proportion of male horses in the population are sterile, because of their social behavior (Garrott and Siniff 1993). By itself, it is unlikely that sterilization (gelding) would allow the BLM to achieve its horse and burro population management objectives since a single stallion is capable of impregnating multiple mares, and stallions other than the dominant harem stallion may also breed with some mares. Therefore, to be fully effective, use of sterilization to control population growth requires that either the entire male population be gathered and treated (which is not practical) or that some percentage of the female wild horses/burros in the population be gathered and treated. If the treatment is not of a permanent nature (e.g., application of the PZP-22 vaccine to mares) the animals would need to be gathered and treated on a cyclical basis.

2.2.2 Alternative 2 - Conger and Frisco HMAs: Gather and Removal Only

Alternative 2 would gather and remove about 150 - 200 excess wild horses from within and outside the Frisco HMA and gather and remove about 200 -250 excess wild horses within and outside the Conger HMA beginning on or about July 1, 2016 to achieve and maintain the AMLs for both HMAs. Based on administrative factors (population estimates, budget, holding space, National gather priorities, etc.) multiple gathers may be conducted within the 10 year life of this document in order to achieve and maintain wild horse populations within the AML and achieve a thriving ecological balance in keeping with the BLM's multiple use mission. Post-gather sex ratios for both HMAs would be expected to remain at 60%/40% males to females.

2.2.3 Alternative 3 - No Action

Under the No Action Alternative, no gather would occur and no additional management actions would be undertaken to control the size of the wild horse population at this time. Populations would be expected to continue growing exponentially from their current sizes, which are far above established AMLs.

2.3 Summary Comparison of Alternatives

<u>Management Actions Common to Alternatives 1-2</u>

- ❑ The research gathers would begin in July 2016 and take about 7 days to complete in each HMA. Several factors such as animal condition, herd health, weather conditions, or other considerations could result in adjustments in the schedule.
- ❑ Gather operations involve areas beyond the HMA boundaries as displayed in Maps 1 and 2.
- ❑ Gather operations would be conducted in accordance with the Comprehensive Animal Welfare Program (CAWP) for Wild Horses and Burro Gathers (Appendix B), which includes provisions of the Comprehensive Animal Welfare Program (BLM Instructional Memorandum 2015-151). The primary gather (capture) methods would be the helicopter drive method with occasional helicopter assisted roping (from horseback). Water trapping could be used in addition, to capture individually selected animals for the research study as well as to address management needs in regards to public safety, emergency situations and private land issues.
- ❑ Trap sites and temporary holding facilities would be located in previously used sites or other disturbed areas whenever possible. Undisturbed areas identified as potential trap sites or holding facilities would be inventoried for cultural resources. If cultural resources are encountered, these locations would not be used unless they could be modified to avoid impacts to cultural resources.
- ❑ Gather operations in Wilderness Study Areas (WSAs) would be conducted by herding animals by helicopter to the temporary gather sites located outside WSA boundaries. No landing of aircraft would occur in WSAs except for emergency purposes and no motorized vehicles would be used in WSAs in association with the gather operation unless such use is consistent with the minimum requirements for management of WSAs and is preapproved by the authorized officer.
- ❑ Decisions to humanely euthanize animals in field situations would be made in conformance with BLM policy (Washington Office Instruction Memorandum 2009-041). Current policy

reference:
http://www.blm.gov/wo/st/en/info/regulations/Instruction_Memos_and_Bulletins/national_instruction/2009/IM_2009-041.html

- ❑ Data including sex and age distribution, condition class information (using the Henneke rating system), color, size and other information may also be recorded, along with the disposition of the animal (removed or released).
- ❑ Hair samples would be collected on all animals returned to the range from each HMA to assess the genetic diversity and pedigree of the herds. Samples would also be collected during future gathers as needed to determine whether BLM's management is maintaining acceptable genetic diversity (avoiding inbreeding depression).
- ❑ If at any time in the future the genetic diversity there is determined to be relatively low, then a large number of other HMAs could be used as sources for fertile wild horses that could be transported into Conger Mountain and Frisco HMAs.
- ❑ Excess animals would be transported to the BLM Delta Wild Horse Facility where they would be prepared (freeze-marked, vaccinated and de-wormed) for adoption, sale (with limitations) or long-term holding.
- ❑ A BLM contract Veterinarian, Animal and Plant Health Inspection Service (APHIS) Veterinarian or other licensed Veterinarian would be on site as the gather is started and then as needed for the duration of the gather to examine animals and make recommendations to the BLM for the care and treatment of wild horses, and ensure humane treatment. Additionally, animals transported to the BLM Delta Wild Horse Facility are inspected by facility staff and the BLM contract Veterinarian, to observe health and ensure the animals have been cared for humanely.
- ❑ Noxious weed monitoring at gather sites and temporary holding corrals would be conducted in the spring and summer of 2017by BLM. Treatment would be provided, if necessary, following guidance from the Noxious Weed Control EA# J-010-099-015EA. Mitigation measures would be followed to eliminate the spread of noxious/invasive weeds as outlined in Noxious Weed Clearance Fillmore Field Office dated December 15, 2009.
- ❑ Monitoring of rangeland forage condition and utilization, water availability, aerial population surveys and animal health would continue.
- ❑ A comprehensive post-gather aerial population inventory would occur within 12 months following the completion of the gather operation. The inventory would be planned to include the Conger and Frisco HMAs and adjacent areas outside HMA boundaries.

Helicopter

If the local conditions require a helicopter drive-trap operation, the BLM would use a contractor or in-house gather team to perform the gather activities in cooperation with BLM and other appropriate staff. The contractor would be required to conduct all helicopter operations in a safe manner and in compliance with Federal Aviation Administration (FAA) regulations 14 CFR § 91.119 and BLM IM No. 2010-164. Helicopter landings would not be allowed in wilderness except in the case of an emergency.

Helicopter drive trapping involves use of a helicopter to herd wild horses into a temporary trap. The CAWP outlined in Appendix B would be implemented to ensure that the gather is conducted in a safe and humane manner, and to minimize potential impacts or injury to the wild horses. Traps would be set in an area with high probability of access by horses using the topography, if possible, to assist with capturing excess wild horses residing within the area. Traps consist of a

large catch pen with several connected holding corrals, jute-covered wings and a loading chute. The jute-covered wings are made of material, not wire, to avoid injury to the horses. The wings form an alley way used to guide the horses into the trap. Trap locations are changed during the gather to reduce the distance that the animals must travel. A helicopter is used to locate and herd wild horses to the trap location. The pilot uses a pressure and release system while guiding them to the trap site, allowing them to travel at their own pace. As the herd approaches the trap the pilot applies pressure and a prada horse is released guiding the wild horses into the trap. Once horses are gathered they are removed from the trap and transported to a temporary holding facility where they are sorted.

If helicopter drive-trapping operations are needed to capture the targeted animals, BLM would assure that an Animal and Plant Health Inspection Service (APHIS) veterinarian or contracted licensed veterinarian is on-site during the gather to examine animals and make recommendations to BLM for care and treatment of wild horses. BLM staff would be present on the gather at all times to observe animal condition, ensure humane treatment of wild horses, and ensure contract requirements are met.

Bait/Water Trapping
Bait and/or water trapping would not necessarily be used, but may be used if circumstances require it. Bait and/or water trapping generally require a longer window of time for success than helicopter drive trapping. Although the trap would be set in a high probability area for capturing excess wild horses residing within the area, and at the most effective time periods, time is required for the horses to acclimate to the trap and/or decide to access the water/bait.

Trapping involves setting up portable panels around an existing water source or in an active wild horse area, or around a pre-set water or bait source. The portable panels would be set up to allow wild horses to go freely in and out of the corral until they have adjusted to it. When the wild horses fully adapt to the corral, it is fitted with a gate system. The acclimation of the horses creates a low stress trapping method. During this acclimation period the horses would experience some stress due to the panels being setup and perceived access restriction to the water/bait source.

When actively trapping wild horses, the trap would be staffed or checked on a daily basis by either BLM personnel or authorized contractor staff. Horses would be either removed immediately or fed and watered for up to several days prior to transport to a holding facility. Existing roads would be used to access the trap sites.

Gathering excess horses using bait/water trapping could occur at any time of the year and traps would remain in place until the target number of animals are removed. Generally, bait/water trapping is most effective when a specific resource is limited, such as water during the summer months. For example, in some areas, a group of wild horses may congregate at a given watering site during the summer because few perennial water resources are available nearby. Under those circumstances, water trapping could be a useful means of reducing the number of horses at a given location, which can also relieve the resource pressure caused by too many horses. As the proposed bait and/or water trapping in this area is a low stress approach to gathering wild horses, such trapping can continue into the foaling season without harming the mares or foals.

Gather Related Temporary Holding Facilities (Corrals)
Wild horses that are gathered would be transported from the gather sites to a temporary holding corral in goose-neck trailers. At the temporary holding corral, wild horses would be sorted into different pens based on sex. The horses would be aged and provided good quality hay and water. Mares and their un-weaned foals would be kept in pens together. At the temporary holding facility, a veterinarian, when present, would provide recommendations to the BLM regarding care and treatment of the recently captured wild horses. Any animals affected by a chronic or incurable disease, injury, lameness or serious physical defect (such as severe tooth loss or wear, club foot, and other severe congenital abnormalities) would be humanely euthanized using methods acceptable to the American Veterinary Medical Association (AVMA).

Transport, Off-range Corrals, and Adoption Preparation
All gathered wild horses would be removed and transported to BLM holding facilities where they would be inspected by facility staff and if needed a contract veterinarian to observe health and ensure the animals are being humanely cared for.

Those wild horses that are removed from the range and are identified to not return to the range would be transported to the receiving off-range corrals (ORC, formerly short-term holding facility) in a goose-neck stock trailer or straight-deck semi-tractor trailers. Trucks and trailers used to haul the wild horses would be inspected prior to use to ensure wild horses can be safely transported. Wild horses would be segregated by age and sex when possible and loaded into separate compartments. Mares and their un-weaned foals may be shipped together. Transportation of recently captured wild horses is limited to a maximum of 12 hours.

Upon arrival, recently captured wild horses are off-loaded by compartment and placed in holding pens where they are provided good quality hay and water. Most wild horses begin to eat and drink immediately and adjust rapidly to their new situation. At the off-range corral, a veterinarian provides recommendations to the BLM regarding care, treatment, and if necessary, euthanasia of the recently captured wild horses. Wild horses in very thin condition or animals with injuries are sorted and placed in hospital pens, fed separately and/or treated for their injuries.

After recently captured wild horses have transitioned to their new environment, they are prepared for adoption, sale, or transport to long-term grassland pastures. Preparation involves freeze-marking the animals with a unique identification number, vaccination against common diseases, castration, and de-worming. At ORC facilities, a minimum of 700 square feet of space is provided per animal.

Adoption
Adoption applicants are required to have at least a 400 square foot corral with panels that are at least six feet tall. Applicants are required to provide adequate shelter, feed, and water. The BLM retains title to the horse for one year and inspects the horse and facilities during this period. After one year, the applicant may take title to the horse, at which point the horse becomes the property of the applicant. Adoptions are conducted in accordance with 43 CFR Subpart 4750.

Sale with Limitations
Buyers must fill out an application and be pre-approved before they may buy a wild horse. A sale-eligible wild horse is any animal that is more than 10 years old or has been offered unsuccessfully for adoption at least three times. The application also specifies that buyers cannot sell the horse to slaughter buyers or anyone who would sell the animals to a commercial processing plant. Sales of wild horses are conducted in accordance with the 1971 WFRHBA and congressional limitations.

Off-Range Pastures
When shipping wild horses for adoption, sale, or Off-Range Pastures (ORPs) the animals may be transported for up to a maximum of 24 hours. Immediately prior to transportation, and after every 24 hours of transportation, animals are offloaded and provided a minimum of 8 hours on-the-ground rest. During the rest period, each animal is provided access to unlimited amounts of clean water and two pounds of good quality hay per 100 pounds of body weight with adequate space to allow all animals to eat at one time.

Mares and sterilized stallions (geldings) are segregated into separate pastures, except at one facility where geldings and mares coexist. Although the animals are placed in ORP, they remain available for adoption or sale to qualified individuals; and foals born to pregnant mares in ORP are gathered and weaned when they reach about 8-12 months of age and are also made available for adoption. The ORP contracts specify the care that wild horses must receive to ensure they remain healthy and well-cared for. Handling by humans is minimized to the extent possible although regular on-the-ground observation by the ORP contractor and periodic counts of the wild horses to ascertain their well-being and safety are conducted by BLM personnel and/or veterinarians.

Euthanasia or Sale without Limitations
While the destruction of healthy excess animals and sale without limitations is allowed under the WFRHBA, neither option is currently available for disposition of excess horses, due to Congressional restrictions in the Department of the Interior's appropriations bills. This appropriations language has been in effect for much of the past twenty years and BLM, accordingly, does not destroy healthy excess animals or allow their sale without limitations.

Any old, sick or lame horses unable to maintain an acceptable body condition (greater than or equal to a Henneke BCS of 3) or with serious physical defects would be humanely euthanized either before gather activities begin or during the gather operations. Decisions to humanely euthanize animals in field situations would be made in conformance with BLM policy (Washington Office Instruction Memorandum (WO IM) 2015-070 or most current edition). Conditions requiring humane euthanasia occur infrequently and are described in more detail in Washington Office Instruction Memorandum 2009-041.

Public Viewing Opportunities
Opportunities for public observation of the gather activities on public lands would be provided, when and where feasible, and would be consistent with WO IM No. 2013-058 and the Visitation Protocol and Ground Rules for Helicopter WH&B Gathers within Utah. This protocol is intended to establish observation locations that reduce safety risks to the public during helicopter gathers

(e.g., from helicopter-related debris or from the rare helicopter crash landing, or from the potential path of gathered wild horses), to the wild horses (e.g., by ensuring observers would not be in the line of vision of wild horses being moved to the gather site), and to contractors and BLM employees who must remain focused on the gather operations and the health and well-being of the wild horses. Observation locations would be located at gather or holding sites and would be subject to the same cultural resource requirements as those sites.

Summary Comparison of the Alternatives

Item	Alternative 1: Proposed Action	Alternative 2	Alternative 3: No Action
• Impacts to Wild Horse Gather Number • Removal Number • Research Treatment (gelding) - # Stallions • Radio Collars and Tags on Marked Animals • Post-Gather Population Size	• Wild horses (gather and removal) would experience handling stress associated with gather operations which would vary by individual and intensity and range from nervous agitation to physical distress. • Stallions gathered in year 2 would be held in the Delta Wild Horse Facility for a short time (expected to be ~7 days or less) • Stallions that would be gelded would experience moderate stress and pain levels from increased handling levels while being sedated and immediately after performance of the gelding procedure. • Mares being fitted with radio collars would have a short acclimation period but would quickly return to normal behaviors based on observationsof captive wild horses at a BLM facility. Males would have a	• Impacts to wild horses gathered and removed would be the same as Alternative 1: Proposed Action • No impacts to wild horses from research study and treatment. • Post gather population would have better access to available space, forage, water, cover and genetic diversity within HMAs for long-term existence.	• No impacts to wild horses from gather operations, or research study. • Population levels would continue to rise above levels that the HMAs could sustain long term. Horses would expand outside established HMAs looking for forage, water, space and cover increasing impacts to those areas where there is no allocation for wild horse use.

	Global Positioning System/VHF radio transmitter tag braided into their tails and would experience no discomfort, nor require an acclimation period. • Post gather population would have access to available space, forage, water, cover and genetic diversity within HMAs for long-term existence.		
Impacts to Rangeland Health Standards/Livestock Grazing/ and Vegetation Resources	• Utilization levels on forage species would be improved compared to current conditions, would be within appropriate utilization levels after the study and AML is achieved and maintained.	• Same as Alternative 1: Proposed Action	• Increased levels of utilization on vegetation resulting in the loss of vegetation/habit at and not in conformance with Rangeland Health Standards

2.4 Alternatives Considered but Dismissed from Detailed Analysis

Use of Bait and/or Water Trapping

It would not be timely, cost-effective or practical to use bait and/or water trapping as the primary gather method to remove the excess horses located within the Conger and Frisco HMAs in order to initiate the research study and achieve near high AML without risking increased degradation to the rangelands. As a result, this alternative was dismissed from detailed analysis.

Remove or Reduce Livestock within the HMA

This alternative would involve no removal of wild horses and instead address the excess wild horse numbers through the removal or reduction of livestock within the HMA. This alternative was not brought forward for detailed analysis because it is outside of the scope of the analysis, is inconsistent with the Pinyon MFP, Warm Springs Resource Area RMP and the WFRHBA, which directs the Secretary to immediately remove excess wild horses, and is inconsistent with BLM's mission of multiple use, sustained yield management, under the Federal Land Policy and Management Act (FLPMA). Livestock grazing can only be reduced following the process outlined in the regulations found at 43 CFR Part 4100. Several reductions and changes have been made to livestock grazing within allotments associated to the Conger and Frisco HMAs

through this process. The elimination of livestock grazing in an area would require an amendment to the Pinyon MFP and Warm Springs Resource Area RMP. Such changes to livestock grazing cannot be made through a wild horse gather decision.

Livestock permit renewals were completed from 2007 – 2014 on the allotments within and adjacent to the Conger and Frisco HMA. Each of these renewals had Environmental Assessments and Decision Records completed. These decisions established stocking rates for livestock. The decisions also established seasons of use, areas of use, kind and class of livestock and management actions to improve livestock distribution. These management actions included the establishment of grazing systems, allowable use levels, salting and herding practices. Some livestock reductions were made in these decisions on allotments within the Frisco HMA. Livestock grazing continues to be evaluated for allotments and use areas within the Conger and Frisco HMAs. Monitoring and evaluation of livestock grazing is in accordance with the Pinyon MFP's Rangeland Program Summary Section IV, 17, which states:

"Rangeland studies and monitoring programs will be continued and/or initiated to determine if rangeland management objectives are being achieved and if proposed grazing use levels must be adjusted. This monitoring program will continue on all allotments. Particular attention will be given those areas where there is high resource conflict or there is the possibility of rapid improvement or deterioration of the rangeland resources. The concentration of rangeland monitoring will be on those allotments in the "I" category.

The monitoring program will evaluate changes in range condition and trend which includes determination of plant vigor, plant character, plant density, plant phenology, ground cover and degree of forage utilization on key species. Four primary studies will be used in this evaluation: (1) actual grazing use, (2) forage utilization, (3) range trend, and (4) climate analysis. In addition, data on wildlife habitat, riparian vegetation, and watershed condition will be collected and used as needed. When results of studies are evaluated and it is determined that the objectives are not being achieved on a specific allotment, modifications could include changes in grazing systems, livestock numbers, season of use, additional rangeland developments, or any combination of these alternatives."

Livestock preference as reflected in existing permits for the allotments that overlap Frisco HMA has remained essentially the same from 1983 to present. For the past ten years actual livestock use with the HMAs has been substantially reduced or even eliminated during the years of drought and during years when the wild horse estimated population was above AML. All of the livestock permits have been renewed through the NEPA process. Adjustments to livestock grazing permits have included seasons-of-use, kind-of-livestock, AUM's, and numbers of livestock, in order to improve or maintain the vegetative condition on the allotments. As livestock grazing permits are evaluated, additional adjustments to the total number of AUM's of specified livestock grazing on each allotment, seasons-of-use, and kind-of-livestock may be made. Detailed information about the authorized livestock use within the HMA is provided in Term Grazing Permit Renewal EAs EA-UT- 040-06-36, DOI-BLM-UT-C010-2011-0034-EA, EA-UT- 040-06-35, and DOI-BLM-UT-W020-2014-0010-EA for those allotments.

The BLM is currently authorized to remove livestock from the HMA. "…if necessary to provide

habitat for wild horses or burros, to implement hard management actions, or to protect wild horses or burros from disease, harassment or injury" under CFR 4710.5. This authority in usually applied in cases of emergency and not for general management of wild horses or burros in a manner that would be inconsistent with the land use plan and the separate decisions establishing the appropriate levels of livestock grazing and wild horse use, respectively. Available data also indicates that wild horse use – including where livestock use has been excluded – has resulted in excessive vegetative utilization and impacts to rangelands that are recovering from wildfire.

Remove and Gather to the Upper AML
A post-gather population size at the upper level of the AML range would result in the AML being exceeded the next foaling season. This would be unacceptable for several reasons.

The AML represents "…that 'optimum number' of wild horses which results in a thriving natural ecological balance and avoids a deterioration of the range" (Animal Protection Institute, 109 IBLA 119;1989). The Interior Board of Land Appeals (IBLA) has also held that, "Proper range management dictates removal of horses before the herd size causes damage to the rangeland. Thus, the optimum number of horses is somewhere below the number that would cause resource damage" (Animal Protection Institute, 118 IBLA 63, 75; 1991).

The upper level of the AML established within a HMA represents the maximum population at which a thriving natural ecological balance would be maintained. The lower level represents the number of animals to remain in a HMA following a wild horse gather, in order to allow for a periodic gather cycle, and to prevent the population from exceeding the established AML between gathers.

Additionally, gathering to the upper range of AML would result in the need to follow up with another gather within one year (with resulting stress on the wild horse population), and could result in overutilization of vegetation resources and damage to the rangeland if the BLM were unable to gather the excess horses in the HMAs on an annual basis. This alternative would not reduce the wild horse population growth rate of 20 - 25 percent in the Frisco and Conger HMAs and the BLM would not be able to conduct periodic gathers and still maintain a thriving natural ecological balance. For these reasons, this alternative did not receive further consideration in this document.

Wild Horse Management Implementing Fertility Control without Removals to Achieve AML
This alternative would not allow for population regulation by removing wild horses to achieve AML on the Conger and Frisco HMAs. Wild horse management under this alternative would involve inoculating mares with PZP or other population growth suppression vaccines. Gather, data collection, and handling techniques would be followed in accordance with the proposed action. Mares inoculated during the summer of 2016 and other years the vaccine was administered would foal normally in the spring following treatment. Reproduction would be limited the following year or years after treatment.

In addition to not meeting the selection criteria for implementing population growth suppression

research, this alternative was eliminated from further consideration due to the inability to achieve population objectives and research needs. The current populations within the Conger and Frisco HMAs exceeds the AML as established in the Pinyon MFP and Warm Springs Resource Area RMP. Implementing population growth suppression without removing wild horses would not address the immediate issue of achieving AML for decades. Population modeling shows that using this alternative with the current immunocontraceptives available would not control the population of wild horses and would not be in conformance with the WFRHBA, Pinyon MFP, and Warm Springs Resource Area RMP. The WFRHBA mandates the BLM to prevent the range from deterioration associated with overpopulation and preserve and maintain a thriving natural ecological balance in consideration with multiple use relationships.

Fertility Control Treatment Only Including Using Bait/Water Trapping to Dart Mares with PZP Remotely (No Removal)

Population modeling was completed to analyze the potential impacts associated with conducting gathers about every 2-3 years over the next 20 year period to treat captured mares with population growth suppression. Under this alternative, no excess wild horses would be removed. Under such an alternative, the use of bait or water trapping would still not remove excess wild horses. While the average population growth would be reduced to about 16% per year, AML would not be achieved and the damage to the range associated with wild horse overpopulation would continue. This alternative would not meet the Purpose and Need for the Action, would be contrary to the WFRHBA, and was dismissed from further study.

The use of remote darting to administer PZP within an HMA where the horses are not accustomed to human activity has been shown to be very difficult. In the Cedar Mountain HMA during a two-year study where administration of PZP by remote darting was to occur, not a single horse was successfully darted. This method has been effective in some HMAs where the wild horses are more approachable, but horses in the Conger and Frisco HMAs are not approachable, so this method of administering PZP was dismissed from further study.

Wild Horse Numbers Controlled by Natural Means

This alternative was eliminated from further consideration because it is contrary to the WFRHBA which requires the BLM to prevent the range from deterioration associated with an overpopulation of wild horses. It is also inconsistent with the Pinyon MFP and Warm Springs Resource Area RMP, which directs the Fillmore and Cedar City Field BLM Offices to conduct gathers as necessary to achieve and maintain the AML. The alternative of using natural controls to achieve a desirable AML has not been shown to be feasible in the past. Wild horses in the Conger and Frisco HMAs are not substantially regulated by predators. In addition, wild horses are a long-lived species with documented foal survival rates exceeding 95% and they are not a self-regulating species. This alternative would result in a steady increase in numbers which would continually exceed the carrying capacity of the range until severe and unusual conditions that occur periodically-- such as blizzards or extreme drought-- caused catastrophic mortality of wild horses.

Use Alternative Capture Techniques Instead of Helicopters to Capture Excess Wild Horses

An alternative using capture methods other than helicopters and bait/water trapping was suggested by the public. As no specific alternative methods were suggested, the BLM identified

chemical immobilization, net gunning, and wrangler/horseback drive trapping as potential methods for gathering horses. Net gunning techniques normally used to capture big game also rely on helicopters. Chemical immobilization is a very specialized technique, is strictly regulated, and also typically relies on helicopters for close access to the animal. Currently, the BLM does not have sufficient expertise to implement either of these methods and they would be impractical to use given the size of the Conger and Frisco HMAs, access limitations and approachability of the horses.

Use of wrangler on horseback drive-trapping to remove excess wild horses can be fairly effective on a small scale, but due to the number of excess horses to be removed, the large geographic size of the Conger and Frisco HMAs, access limitations and approachability of the horses this technique would be ineffective and impractical. Horseback drive-trapping is also very labor intensive and can be very harmful to the domestic horses and the wranglers used to herd the wild horses. For these reasons, this alternative was eliminated from further consideration.

Gather and Release Excess Wild Horses Every Two Years and Apply PZP to Horses for Release

Another alternative considered was to gather a substantial portion of the existing population (90%) and implement population growth suppression treatment only, without removal of excess horses was modeled using a two-year gather/treatment interval over a 10 year period. PZP pellets that were intended to work for 22 months have been shown in recent pen trials to actually be effective for only one year. Based on WinEquus population modeling (See Appendix D), this alternative would not result in attainment of AML for the HMAs. The wild horse population would continue to have an average population growth rate of 5% to 15% on Conger and 4% to 12% on Frisco, adding to the current wild horse overpopulation, albeit at a slower rate of growth than the No Action Alternative. The modeling reflected an average population size in 11 years of 343 to 1497 wild horses on Conger and 381 to 710 wild horses on Frisco under a two year treatment interval. None of the trials in this alternative would decrease the existing overpopulation of wild horses, resource concerns and rangeland deterioration would continue, and implementation would result in substantially increased gather and population growth suppression costs relative to the alternatives that remove excess wild horses to the AML range. In addition to not achieving AML, the time needed to complete a gather would also increase over time, because the more frequently an area is gathered, the more difficult wild horses are to trap. They become very evasive and learn to evade the helicopter by taking cover in treed areas and canyons. Wild horses would also move out of the area when they hear a helicopter, thereby further reducing the overall gather efficiency. The horses would also become so wary of traps used in water or bait traps that they would avoid any waters where traps are or were set up. Frequent gathers would increase the stress to wild horses, as individuals and as entire herds. It would become increasingly more difficult over time to repeat gathers every two years to successfully treat a large portion of the population. For these reasons, this alternative was dropped from detailed study.

3.0 Affected Environment

This section of the EA briefly discusses the relevant components of the human environment which would be either affected or potentially affected by the Action Alternatives or No Action (refer to Table 2). Direct impacts are those that result from the management actions while indirect impacts are those that exist once the management action has occurred.

3.1 General Description of the Affected Environment

Frisco HMA

The Frisco HMA is approximately 60,367 acres and is located approximately 15 miles northwest of Milford, Utah (Map 1). Access is provided to the HMA by several dirt roads that originate from Utah State Highway 21. However, the condition of the roads can very on a daily basis due to weather conditions. Temperatures range from 105°F in the summer, to sub-zero in the winter. The wild horses primarily use the lower benches in the winter and the higher elevations in the summer. The HMA is heavily forested with pinyon/juniper trees. The soils within the area are primarily loams. There are considerable amounts of surface rock and scattered rocky outcrops within canyons resulting in wild horses having difficulty traveling long distances and having to take circuitous routes between forage and water.

The HMA ranges from 5,600 feet in the valleys to 9,500 feet in elevation at the top of Frisco Peak. The HMA supports vegetation types of big sagebrush and pinyon/juniper. The pinyon/juniper vegetation type dominates the HMA and can be dense with minimal understory forage. Open areas outside of the pinion/juniper canopy are dominated by sagebrush/grasslands. Indian ricegrass (*Oryzopsis hymenoides*), needle-and-thread grass (*Stipa comata*), and small amounts of curlygrass (*Hilaria jamesii*) are the primary forage species. Forage has been suffering from drought conditions of below normal precipitation in 2007, 2008, 2009, 2012, 2104 and 2015. Spring moisture in 2015 was only 50% of normal, which reduced both water flows at springs and forage production. Forage conditions have not made sufficient improvement since 2012. Minimal vegetative growth of plants and heavy grazing have already reduced much of the available vegetation. Vegetation near water has been impacted heavily.

The HMA has twelve springs. Five of the springs are developed with the rest undeveloped. Most of these water sources were dry in 2015. Only three springs (Dipper, Moorehouse, and High Rock Springs) have sufficient water to sustain wild horses and wildlife through the summer. Dipper and High Rock Springs are in the northeast portion of the HMA. Moorehouse spring is in the central eastside of the HMA. This limits the wild horse movement to the east side of the HMA. These springs also rely on pipelines and troughs to provide the water sources for the wild horses. Currently the pipelines and troughs are in working order, but if they fail these sources could go dry quickly.

There are estimated to be 288 wild horses within the HMA at present with 29 of these being yearlings (last year's foals). As forage within close proximity of water sources is depleted, the wild horses will need to range greater distances for forage. The distance the animals must travel can result in rapid physical deterioration of the animals. In addition, an overlapping dependence of wildlife for the same habitat as wild horses, necessitates action to reduce competition for

limited resources and to preserve physical condition of all animals. Rather than maximizing the number of a single species on the range, it is within BLM's multiple use mission to ensure, as much as possible, that forage and water are adequate to sustain healthy populations of native wildlife as well as horses.

Conger Mountain HMA

The Conger Mountain HMA is approximately 151,506 acres of public and private land, and is located approximately 20 miles northeast of Garrison, Utah (Map 2). Access is provided to the HMA by several dirt roads that originate from Utah State Highways 6 and 50. However, the condition of the roads can very on a daily basis due to weather conditions. Temperatures range from 100°F in the summer, to sub-zero in the winter. The wild horses primarily use the lower benches and valley bottoms in the winter and the higher elevations in the summer. The HMA has some forested areas comprised of pinyon/juniper trees primarily along ridge tops and across Conger Mountain. The soils within the area are primarily loams. Terrain features may require horses to travel several miles between water and forage along well defined trails.

The HMA ranges from 5,200 feet in the valleys to 8,070 feet in elevation at the top of Conger Mountain. The HMA supports vegetation types of black sagebrush and pinyon/juniper. Open areas outside of the pinyon/juniper sites are dominated by blacksage/grasslands. There are a few juniper trees that occur on the valley floors and low hills among the blacksage/grasslands. Key species include indian ricegrass (*Oryzopsis hymenoides*), bottlebrush squirreltail (*Sitanion hystrix*), galletta (*Hilaria jamesii*), needle-and-thread grass (*Stipa comata*), sand dropseed (*Sporobolus cryptandrus*) and winterfat (*Ceratoides lanata*). Forage has been suffering from drought conditions of below normal precipitation in 2008, 2009, 2010, 2012, 2104 and 2015. Winter and spring moisture in 2015 was only 50% of normal which reduced both water flows at springs and forage production. Forage conditions have not made sufficient improvement since 2012. Minimal vegetative growth of plants and heavy grazing have already reduced much of the available vegetation. Vegetation near water has been impacted heavily.

The HMA has four major springs that have been developed providing water storage across the HMA. These springs (Conger, Skunk, Willow, and Knoll Springs) provide permanent water to sustain wild horses and wildlife through the summer. Skunk and Willow Springs are in the north portion of the HMA. Conger Spring is in the central and Knoll Spring is on the west side of the HMA. Skunk and Conger Springs have been developed with pipelines and a series of storage tanks and troughs to provide the water sources for the wild horses, wildlife and livestock during authorized grazing seasons. The northern portion of the HMA, including the WSA, has been designated as crucial habitat for wild horses. Skunk, Willow and the upper Conger Springs are located within this designation and all available surface water is available for wild horses and wildlife. Livestock grazing in the crucial habitat is limited to sheep only. All authorized cattle grazing takes place within the open portion of the HMA where water is piped to storage tanks and troughs.

There are estimated to be 310 wild horses within the HMA at present with 50 of these being yearlings (last year's foals). As forage within close proximity of water sources is depleted, the wild horses will need to range greater distances for forage. The distance the animals must travel can result in rapid physical deterioration of the animals. In addition, an overlapping dependence

of wildlife for the same habitat as wild horses, necessitates action to reduce competition for limited resources and to preserve physical condition of all animals. Rather than maximizing the number of a single species on the range, it is within BLM's multiple use mission to ensure, as much as possible, that forage and water are adequate to sustain healthy populations of native wildlife as well as horses.

3.2 Description of Affected Resources

Elements of the human environment identified as present and potentially affected by at one of the alternatives include livestock grazing, rangeland health standards (including soils, vegetation and riparian), wild life and wild horses. The existing situation (affected environment) relative to these resources is described below. Other resources considered which would not be affected by the alternatives are described in Appendix E.

Livestock Grazing

The Skunk Springs, Ledger Canyon, Conger Spring, Buckskin, Painter Spring, Browns Wash, Crystal Peak, Red Rock, Beaver Lake, Frisco, and Wah Wah Lawson allotments are within the two HMAs. There are a total of 18 livestock operators who are currently authorized to graze livestock in these allotments annually. The operators are authorized to use 40,021 Animal Unit Months (AUMs) of forage each year. An AUM is the amount of forage needed to sustain one cow, five sheep, or five goats for a month. The allotments consist of various pastures grazed in rest-rotation and deferred rotation grazing systems. The season of use may vary by 1-2 weeks annually based upon forage availability, drought conditions, and other management criteria.

The BLM allocated forage for livestock use and AML for the Conger HMA was established as a population range 40 – 80 through the Warm Springs Resource Area RMP ROD, 1987. The BLM allocated forage for livestock use and as suitable for wild horses in the Pinyon Management Framework Plan (PMFP) (1983). The Frisco Herd Management Area Plan (2012) provides direction for management specific to the Frisco HMA and adjusted the AML to 30-60. Adjustments in permitted use have been made through Allotment Management Plans and permit renewals as conditions have changed such as drought and class of livestock changes. The following table summarizes the livestock use information for the allotments in the HMA.

Livestock Use

Allotment	Total Allotment Acres	% of Allotment in HMA	Permittee	Livestock	Authorized Season of Use	% Public Land	Authorized Livestock AUMs (Preference Entire Allotment)
Conger HMA							
Skunk Springs	37,061	15%	1 2	1372 Sheep 22 Cattle	11/09 – 04/15 05/10 – 10/15	100% 100%	1426 115
Ledger Canyon	17,811	12%	1	1957 Sheep	11/16 – 04/15	90%	1749
Conger Spring	70,425	34%	1	526 Sheep 316 Cattle	11/01 – 5/10 11/01 – 5/10	80% 85%	581* 1826
Buckskin	21,898	14%	1	2062 Sheep	11/16 – 04/30	100%	2264
Browns Wash	26,112	17%	1	2017 Sheep	11/01 – 04/30	86%	2003
Painter Spring	33,486	8%	1	1947 Sheep	11/01 – 04/15	100%	2125
Crystal Peak	69,099	28%	1 2	403 Sheep 3700 Sheep	11/01 – 04/30 10/14 – 04/30	100% 91%	430 4361
Frisco HMA							
Red Rock	20,769	8%	1	2465 Sheep	03/01 – 04/30	81%	801
Beaver Lake	71,901	31%	1	496 Cattle 100 Cattle	11/01 – 05/31 06/0/ - 06/30	100% 100%	3457 99
Frisco	65,227	23%	1	2640 Sheep 1800 Sheep 50 Cattle	10/16 – 03/31 04/01 – 05/31 10/16 – 05/31	92% 92% 100%	2683 664 376
Wah Wah Lawson	141,180	11%	1	335 Cattle 1280 Cattle 1100 Cattle	10/01 – 10/15 10/16 – 02/28 03/01 – 06/15	87% 87% 87%	144 4999 3367

*AUMs are the same. Operator does not use sheep AUMs (581 sheep AUMs in nonuse).

Rangeland Health Standards

The Standards for Rangeland Health address the potential for soil erosion (Standard 1. Upland soils exhibit permeability and infiltration rates that sustain or improve site productivity, considering the soil type, climate, and landform), the health of riparian and wetland areas (Standard 2. Riparian and wetland areas are in properly functioning condition. Stream channel morphology and functions are appropriate to soil type, climate and landform), the maintenance of desired species (Standard 3. Desired species, including native, threatened, endangered and special-status species, are maintained at a level appropriate for the site and species involved) and water quality (Standard 4. BLM will apply and comply with water quality standards established by the state of Utah (R3172) and the federal clean water and safe drinking water acts.). Standards 1-3 are addressed below and in other sections, while standard 4 is not addressed as this standard was being met on both HMAs and the quantity of surface water in these HMAs is very limited.

Soils

Soils within the proposed gather area are highly variable in terms of parent material, erosion potential, productivity and other aspects. Detailed soil descriptions and maps may be found in the Soil Survey of Beaver County, Utah and West Millard-Juab Area, Utah (Natural Resource Conservation Service (NRCS), 1996).

BLM is required to keep an inventory of how well grazing allotments are meeting Utah BLM's Rangeland Health (RLH) Standards, which includes rating soil conditions in terms of current conditions and causal factors for those conditions. The results of RLH assessments are the basis of soils analysis for this proposal. RLH Standard 1 requires productive upland soils as evidenced by sufficient cover and litter to protect soil surfaces from erosion, the absence of erosion indicators and appropriate kind and amounts of vegetation to allow properly functioning ecological conditions. The Key Forage method has been used as recently as spring 2015 to monitor how much vegetation has been removed (primarily by large ungulates), and may be used to reflect whether or not adequate protective vegetation cover and litter has been left on-site to protect soils surfaces from erosion.

Vegetation

Rangeland Health Studies have been completed on all of the livestock grazing allotments that are or have a portion of the allotment within the Conger and Frisco HMA. These studies can be found within the allotment files at the BLM Fillmore and Cedar City Field Offices. The methodology of each study was completed using technical reference 1734-6. Vegetation production and vigor has been reduced by drought (Standard and Guideline Studies). Drought is defined as prolonged dry weather generally when precipitation is less than 75% of average annual amount (Society for Range Management 1974). Precipitation is the most important single factor determining the type and productivity of vegetation in an area. Forage production increases rapidly as precipitation increases up to about 20 inches per year (Holechek, 1989). Slight reduction from normal precipitation can cause severe reductions in plant yield in areas with less than 12 inches of precipitation (Klages 1942). The valleys within the Conger and Frisco HMA average less than 8 inches per year. During the period from 2007-2009 the precipitation was below 75% for that area. Need to update precipitation information.

The current drought cycle has had a tremendous influence on rangeland vegetation. As described above, year-long grazing by wild horses has put additional stress on key forage species already affected by drought. Some key forage species have been lost. Recovery could take 5 to 15 years, depending on how severely the drought affected a particular area. Two or more years of drought have far greater impact on vegetation than one year of drought followed by normal or above-normal precipitation.

The Conger and Frisco HMA supports multiple vegetation types including: Pinyon-Juniper (PJ), sagebrush, salt brush and grasslands. The PJ woodland type dominates the Frisco HMA and is very dense with minimal understory forage. Open areas outside the PJ canopy are dominated by big sagebrush with Indian ricegrass, wheatgrass, bluegrass, and squirreltail grass as the primary forage species. Only 12% of the HMA produces forage that can be used by ungulates, with only 3% of the HMA considered to be good forage production area. The Conger HMA has more open areas dominated by salt brush and grasslands producing more forage.

Monitoring data collected within the Frisco HMA indicated the Utah BLM Standards and Guidelines for Healthy Rangelands were not being fully met and that causal factors for non-attainment of Standard 2 and 3 include dewatering of riparian resource, excessive use by wild horses and elk, the prevalence of invasive species including cheatgrass and halogeton, pinyon and juniper tree encroachment, historic livestock grazing and climatic conditions (drought).

Utah BLM Standards and Guidelines for Healthy Rangelands are being met, but the causal factors (i.e. climatic conditions and wild horse and livestock grazing) are contributing to the plant communities not being able to maintain "*viable levels commensurate with the species and habitats potential*" within the Conger HMA. During the past several years, climatic events have occurred at critical times which have allowed the habitat to respond positively but continued drought conditions are evident within the plant communities.

Utilization studies that have been completed during the past 20 years, along with CCFO/FFO staff observations, suggest that as wild horse populations increase they contribute to the decrease of forage species. This is especially true in grassland, sagebrush/grassland, and seeded areas. The High Rock seeding has been overtaken by PJ woodland and sagebrush with little grass understory left. The Frisco fire continues to be primarily grasses, but no utilization studies have been completed on it due to its remoteness.

Utilization studies completed on the Beaver Lake Allotment at the end of June, 2012, showed that in a pasture used only by cattle the utilization on Indian Ricegrass was Slight (13%), while the two adjacent pastures that received use by cattle and wild horses was Moderate to Heavy use (41%-65%).

Seven trend studies were set up within and adjacent to the Frisco HMA by the BLM. These studies describe the soils as being in a stable trend with browse trending slightly down and herbaceous species trending from slightly down to slightly up depending on location within the HMA. These Frequency trend studies suggest the trend is in general stable or static condition. Additional information on the vegetation studies have been summarized in Term Grazing Permit Renewal EAs for the allotments within the HMA.

Year-long grazing by wild horses has been one contributing factor to the downward trend of the grasses and the change from cool season grasses to warm season grasses. Horses, because they are territorial, are grazing the same areas repeatedly throughout the spring during critical growing periods for grasses. High populations of wild horses can reduce the available forage for not only the year the grasses are grazed, but also for years to come. Horses will graze the most desirable forage plants first before grazing on other species. Wild horses are capable of cropping forage much more closely than wild or domestic ruminants, causing a loss of the most desirable forage species and reducing plant diversity.

From 1998 to 2003 and 2008 to present the excess number of wild horses (numbers over AML) within the HMA reduced the amount of available forage for all grazing animals.

Riparian/Wetland

Several small wetland/riparian areas are present within the Frisco HMA and consist of streams, seeps, and springs that all occur on BLM lands. There are approximately 0.5 miles of lotic (stream) habitat and a total of approximately 2.6 acres of lentic (spring/seep) areas in the Frisco HMA that have been inventoried. An unknown amount of riparian/wetland area that occurs within the Frisco HMA still needs to be inventoried. Common riparian/wetland species are willows, cottonwoods, sedges, rushes, Woods rose, and Kentucky bluegrass. The riparian/wetland areas that have been inventoried since 1995 have approximately 0.9 acres rated in proper functioning condition, 0.23 acres rated as functioning at risk with no apparent trend, 0.86 acres functioning at risk with downward trend, and 0.5 linear miles and 0.67 acres rated as nonfunctional. Riparian habitats represent less than 1 percent of the total acreage of public lands in the Frisco HMA. Reptiles, amphibians, mammals, and bird species routinely use riparian areas for food, water, cover or migration routes. Many neotropical migratory birds are riparian obligates.

Lentic Resources for Frisco HMA

		Riparian Functional Rating – Acres of Riparian					
Site Name	Year Assessed	PFC	FAR-UP	FAR-NA	FAR-DN	NF	Total
Bardsley Spring	2006	0.01					0.01

Frisco HMA LoticTotal Miles						0.5	0.5
Percent of Total Miles						0.5	100%

PFC=Proper Functioning Condition FAR-UP= Functional at risk with upward trend
FAR-NA= Functional at risk, trend not apparent FAR-DN= Functional at risk with downward trend
NF= Non-functional

Causal Factors

The rationale for the less than PFC rating was water development, dewatering, road encroachment, upstream channel conditions, juniper encroachment, rabbitbrush encroachment, recreation, and riparian exclosure maintenance. Livestock, wild horses, and wildlife were also noted as causal factors for portions of the streams not rating at PFC. Wild horses, wildlife, and livestock graze riparian areas due to the presence of water, shade, and succulent vegetation. Riparian areas are vulnerable to the effects of overgrazing due to heavy concentration of wild horses, wildlife, and livestock within these areas. Livestock, wildlife, and wild horse grazing impacts water in many ways. Grazing impacts can alter the chemical, physical and biological integrity of the water. Grazing impacts also have the ability to modify the hydrologic response of watersheds by reducing infiltration, reducing vegetative cover, stream channel/floodplain degradation, accelerated erosion processes, surface roughness, and increase compaction. All of these impacts are known to occur, but the impacts cannot be quantified in a predictive manner. Many of the causal factors are within the control of management.

Riparian-wetland areas support a wide variety of avian fauna, mule deer, elk, pronghorn, greater sage grouse, Townsend's big-eared bat and many other small mammals, reptiles, and amphibians. Riparian-wetland resources provide food, shelter, breeding ground, and migration corridors for a variety of wildlife species. Mule deer and elk are attracted to riparian areas due to cooler summer temperatures, valuable forage, water availability and, in treed sites, the ability of the communities to provide hiding cover as well as thermal cover in the winter. Lowland riparian areas provide a valuable source of water and succulent forage for pronghorn. Mule deer utilize riparian-wetland areas during fawn rearing because riparian vegetation along springs, streams, meadows, and aspen stands are a source of succulent grasses and forbs; which provide important nutrition during gestation and lactation.

Below are photos of Armstrong Spring in 1995 (wild horse population within AML) and in 2012 (368% over upper AML). The only use that occurs on Armstrong Spring is wild horses, a few elk and occasional non-permitted livestock.

Armstrong Spring 1995
Non-Functioning with upward trend.

Armstrong Spring 2012
Non-Functioning with downward trend

Wild Horses

The Frisco HMA was formally designated as a Herd Management Area (HMA) through the Pinyon Management Framework Plan (PMFP), 1983, which allows for, "the removal of horses as required to maintain horse numbers at or below 1982 inventory levels, but not less than 1971 levels." The Frisco Herd Management Area Plan (2012) provides direction for management specific to the Frisco HMA. The Frisco HMAP can be found at the following link: http://www.blm.gov/style/medialib/blm/ut/natural_resources/wild_horses_and_burros/frisco.Par.53144.File.dat/FriscoFinalEA.pdf.

The Conger Mountain HMA was formally designated as a Herd Management Area (HMA) through the Warm Springs Resource Area RMP/ROD, 1987. AML was established through site vegetation inventory monitoring and data collection as a population range 40 - 80 in the Warm Springs Resource Area RMP/EIS, 1986. The following table summarizes the AML, estimated population, and estimated removal numbers for the HMAs under the Proposed Action.

Summary of Wild Horse Population Information

HMA	Acres	AML Range	Estimated Pop.	Proposed Target Gather	Proposed Target Remove	Target Treat, Yr 2 (# Studs)	Adjust Sex Ratio (% Studs)	Estimated Post Gather Pop. Size
Frisco	60,367	30 - 60	345*	300	245	0	50	100
Conger Mtn.	170,990	40 - 80	372*	330	272	25-35	50	100

* Population estimates as of March 2016 include the 20% population increase of 2016 foals based on population inventories completed in February 2016. Based on the National Academy of Science (NAS) report released in 2013 the estimated population could be 20%-30% lower than the actual population.

Utilization levels by wild horses on the rangelands within the HMAs have shown increases as the

population has increased. Potential for loss of key forage species has increased as the amount of sustainable forage is depleted through higher levels of use. The past two years have exhibited unfavorable climatic conditions that have had below normal to precipitation, but cooler temperatures and timely rain events have allowed key vegetative species to survive. Drought events over the past ten years have shown the effects of limited resources for wild horses through body condition and range condition. Areas outside the HMAs are experiencing increased un-allotted use on forage species and resources by wild horses which have expanded outside the HMAs. Excess wild horses above AML need to be removed in order to protect the resources outside the HMAs and those resources within the HMAs to allow for proper rangeland health and herd sustainability.

Wild horses within the Conger and Frisco HMAs are currently in moderately thin to moderate body class conditions or a body condition score (BCS) class 3 – 5 on the Henneke BCS chart. Increased utilization levels have been observed by wild horses within key areas, which adversely impacts range health and inhibits recovery of the native vegetative communities in these key areas. Monitoring also indicates that wild horses have moved and are residing outside the HMA boundaries.

The genetic variability of the Conger Mountain HMA is high. According to the "Genetic Analysis of the Conger, Ut HMA" conducted by Dr. E. Gus Cothran published June 30, 2009, "the values related to the allelic diversity in particular suggest a herd with highly mixed ancestry. This view is consistent with the similarity values seen and the heterozygosity measures. The herd ancestry most likely is from North American breeds." The results indicated that genetic diversity in the Conger Mountain HMA is not unique. Moreover, if at any time in the future the genetic diversity there is determined to be relatively low, then a large number of other HMAs could be used as sources for fertile wild horses that could be transported into Conger Mountain HMA.

Blood samples for genetic testing were taken in 2006 to create a baseline for the wild horses that occur within the Frisco HMA. Hair samples for genetic testing were collected and analyzed in 2012 by Dr. Gus Cothran and Texas A&M University. The report released in 2013 states that the genetic variability of the Frisco HMA in general is on the high side but there is a high percentage of variation that is at risk. The herd appears to be in genetic equilibrium. There is no evidence of gene flow into the herd or of recent low population size. Genetic similarity results suggest a herd with mixed ancestry. No action is needed at this point to maintain genetic variability, but the herd should be monitored closely. Hair samples would be collected on both the Conger and Frisco HMAs for genetic analysis.

Wildlife

No federally listed threatened, endangered or candidate species have been identified within the Conger and Frisco HMAs and they will not be discussed further in this document.

BLM Sensitive Wildlife Species

The following list summarized the Special Status Wildlife Species (excluding species listed

under ESA) recognized by management under BLM's 6840 Manual and Instruction Memorandum No. UT2007-078. These species are known to occur or have a high probability of occurrences within the Conger or Frisco HMAs.

Ferruginous Hawk *(Buteo regalis):* The Ferruginous hawk may occur within the Conger or Frisco HMAs. Primary breeding habitat is pinyon-juniper and secondary breeding habitat is shrub-steppe. Edges of pinyon-juniper woodland, utility structures (transmission poles), cliffs and isolated trees serve to provide nesting as well as perching structures for ferruginous hawk.

Townsend Big-Eared Bat *(Corynorhinus townsendii)*: Townsend big-eared bat primary breeding habitat consists of pinyon-juniper woodlands and mountain shrub communities. Small moths and a variety of soft-bodied insects are typical food habits.

Big Game

Mule Deer *(Odocoileus hemionus*: Mule deer habitats in the Conger and Frisco HMAs have been identified as crucial winter range. During spring, summer and early fall, deer fed primarily on a variety of forbs and grasses, with light use on big sagebrush, black sagebrush and antelope bitterbrush. In fall and winter, deer shift their diets to shrubs including big sagebrush, black sagebrush, antelope bitterbrush, Gambel oak and curlleaf mountain mahogany.

Rocky Mountain Elk *(Cervus Canadensis)*: The Frisco HMA has been identified as yearlong elk habitat. Elk primarily forage on grasses, but also utilize shrubs, trees and forbs.

Pronghorn *(Antilocapra Americana)*: Pronghorn typically utilize a variety of vegetation with shrubs being highest in composition followed by forbs and grasses. The Conger and Frisco HMAs have been identified as yearlong pronghorn habitat.

Upland Game

Chukar *(Alectoris chukar)*: Chukar prefers to inhabit open, rocky mountain slopes and forage on seeds from a variety of shrubs, grass and forbs within the Conger and Frisco HMAs.

Migratory Birds and Raptors

The Migratory Bird Treaty Act (16 U.S.C. §703-712, July 3, 1918, as last amended in 1989) prohibits taking, killing, or possessing migratory birds including nests and eggs. In 2001, Executive Order 13186 was issued to outline responsibilities of federal agencies to protect migratory birds under the Migratory Bird Treaty Act (66 FR 3853-3856). Instruction memorandum 2008-050 provides interim guidance to enhance coordination and communication towards meeting BLM's obligations to the Migratory Bird Treaty Act and Executive Order 13186.

BLM entered into a Memorandum of Understanding (BLM- MOU WO-230-2010-04) with USFWS to promote the conservation of migratory birds; specifically, *to strengthen migratory*

bird conservation by identifying and implementing strategies that promote conservation and avoid or minimize adverse impacts on migratory birds through enhanced collaboration between the Parties, in coordination with state, tribal, and local governments.

Golden Eagle (Aquila chrysaetos)
Golden eagles may occur on the Conger and Frisco HMAs year round. The SWreGAP Animal Habitat Model has shown know or probable winter habitat. A majority of the HMAs would be used for foraging.

Health and Safety

In recent gathers, members of the public have increasingly traveled to the public lands to observe BLM's helicopter gather operations. Because these horses are wild animals, there is always the potential for injury when individuals get too close or inadvertently get in the way of gather activities. The helicopter work is done at various heights above the ground, from as little as 10-15 feet (when herding the animals the last short distance to the gather corral) to several hundred feet (when doing a recon of the area). When the helicopter is working close to the ground, the rotor wash of the helicopter is a safety concern by potentially causing loose vegetation, dirt, and other objects to fly through the air which can strike or land on anyone in close proximity as well as cause decreased vision. During the herding process, wild horses or burros will try to flee if they perceive that something or someone suddenly blocks or crosses their path. The public would not be allowed to view the actual trapping activities during bait or water trapping, as described in Section 2.3. Safe viewing areas would be identified for the public to view loading, and sorting. Public observation of the helicopter gather activities on public lands will be allowed and would be consistent with BLM IM No. 2010-164 and in compliance with visitation protocols for scheduled and non-schedule visitation.

4.0 Environmental Consequences

4.1 Introduction

This section of the EA documents the potential environmental impacts which would be expected with implementation of the Action Alternatives (Alternatives 1-2), and/or the No Action Alternative. These include the direct impacts (those that result from the management actions) and indirect impacts (those that exist once the management action has occurred).

4.2 Potential Impacts

The direct and indirect impacts to these resources which would be expected to result with implementation of the Action Alternatives or No Action Alternative are discussed in detail below.

Livestock Grazing

Alternatives 1 and 2

Livestock located near gather activities may be temporarily disturbed or displaced by helicopter use and increased vehicle traffic during the gather operation. This displacement would be temporary and the livestock would move back into the area once gather operations moved. Past experience has shown that gather operations have little impacts on grazing cattle and sheep.

Indirect impacts to livestock grazing would be an increase in forage availability and quality, reduced competition for water and forage, and improved vegetative resources that would lead toward a thriving ecological condition over the course of 6 to 10 years.

Annual authorized livestock use may be adjusted due to a number of factors, including rangeland health or drought. Managing wild horses at the AML through gather and removals with or without Population growth suppression would help with long-term sustainability of authorized livestock use within the HMAs at the permitted levels. Managing wild horses within AML would reduce the likelihood of adjustments to current active livestock permits attributable to overuse of resources by wild horses. This action would have no direct impact on current livestock permits in terms of active AUMs, season of use and/or terms and conditions. The fences would provide better control of livestock from getting on Highway 21 and causing livestock/vehicle collisions. Adjustments to livestock permits (if any) would be made during the livestock allotment permit renewal process.

Alternative 3 (No Action)

Utilization by authorized livestock has been directly impacted due to the current overpopulation of wild horses, both within and outside the HMA boundaries. Livestock operators have been asked to take voluntary reductions due to the impacts of the wild horse population on range vegetation/forage conditions. The current wild horse population is 3-5 times above their forage allocation. Moderate to heavy utilization is occurring. The indirect impacts of No Action (Defer Gather and Removal) would be continued damage to the range, continuing competition between livestock, wild horses and wildlife for the available forage and water, reduced quantity and quality of forage and water, and undue hardship on the livestock operators who would continue to be unable to fully use the forage they are authorized to use.

Rangeland Health Standards

Alternatives 1 and 2
Rangeland Health Standards are directly impacted by the levels of use experienced upon upland soils, riparian and wetland areas, desired plant species including native, threatened, endangered and special status species. The Standards for Rangeland Health indicate that, under alternatives 1 or 2, the potential for soil erosion would be reduced (Standard 1. Upland soils exhibit permeability and infiltration rates that sustain or improve site productivity, considering the soil type, climate, and landform) and riparian areas would receive less grazing pressure which in turn would reduce the impacts to these riparian areas (Standard 2. Riparian and wetland areas are in properly functioning condition. Stream channel morphology and functions are appropriate to soil type, climate and landform) and would contribute to the maintenance of desired species (Standard 3. Desired species, including native, threatened, endangered and special-status species, are maintained at a level appropriate for the site and species involved). Therefore, the potential for maintenance of rangeland health would be increased by removing the wild horses to keep their numbers on the HMA at levels that are closer to the appropriate management level. If no action is taken, rangeland health will deteriorate in areas where wild horses spend most of their time. Riparian vegetation would be affected and soil erosion would increase as desired vegetation is removed from the range. A reduction in the number of wild horses to the appropriate management levels within the HMA boundaries would allow increased maintenance of rangeland health. Over time as population levels are managed at AML, rangeland health would continue to improve allowing for the thriving ecological condition of all uses present.

Alternative 3 (No Action)
Deterioration of rangeland health would continue to increase as population levels increase with no action. Those areas where wild horses spend a majority of their time would suffer from the loss of riparian vegetation, increased soil erosion and compaction and the desired plant species are removed from the range. Indirect impacts from no action would occur in areas not suitable for wild horses. These areas outside the HMAs would experience increased levels of use and may not be resilient enough to recover. Wild horses exist within the HMAs because their basic needs of water, desirable vegetation, cover and space are met. Areas outside the HMAs lack some if not all of these needs and would suffer from increased use.

Soils

Alternative 1 (Proposed Action)
The Proposed Action would have a direct impact to soils directly in the trap area. These areas would be disturbed by the hoof action of wild horses when they are concentrated in the trap area to be loaded on the trailers. The disturbance would be ¼ to ½ acre in size at each trap and would normally be in areas already disturbed like a road, wash, or previous trap site. Most operations would occur when soils are dry or frozen reducing the impact to soils. Past trap site locations have recovered within a year with vegetation to stabilize the soils. No compaction of soils have occurred from past gather operations.

This analysis assumes that livestock use would continue at levels as established by grazing permit renewal decisions, big game numbers would continue as established by herd management

plans and state law and removal of wild horses would be as proposed to within the AML levels specified for the HMA at the end of the 10 year period.

The proposed action would have the indirect impact of aiding eleven grazing allotments (Skunk Springs, Ledger Canyon, Conger Spring, Buckskin, Browns Wash, Painter Spring, Crystal Peak, Red Rock, Beaver Lake, Frisco, Wah Wah Lawson) to move towards attainment or maintenance of Rangeland Health Standard 1. In general, the reduction of wild horses to proposed levels would reduce utilization levels, which would allow more residual vegetation and litter to remain on site and protect the soil resource. Increased litter would provide additional protection from wind and water erosion, promote infiltration, detain surface flows and retard soil moisture loss by evaporation, thus allowing for better vegetative productivity. Indicators, such as pedestals, bare ground, litter movement, flow patterns, etc. should lessen with implementation of the proposed action. Further, reduced numbers of horses should result in less compaction of wet sites, such as riparian areas and enhance soil and vegetation production there.

Alternative 2 (Gather and Removal Only)
Impacts to the soil resource would be essentially the same under Alternative 2 as under the Proposed Action Alternative. Protective vegetative cover and soil surfaces would respond as well as under the Proposed Action, or even better because Alternative 2 leads to the horse population reaching AML at an earlier date.

Alternative 3 (No Action)
Under the No Action Alternative, wild horse populations would continue to increase beyond the capacity of the habitat to provide water and forage. Heavy and severe use of desirable vegetation resources by wild horses would continue and increase. Horses are opportunistic feeders and as their populations increased, may eventually have to choose non-forage species, such as three-awn grass, rabbitbrush and junipers for their survival, which would result in even less litter and residual vegetation left on site than under the current situation. Current indicators of poor soil conditions would remain on allotments currently not meeting Rangeland Health Standards. Additional indicators, such as increased overland flows, rills and gullies could occur as additional soil was lost from the allotments. Wind erosion could become a factor, where it is not currently. Horses would have to expand their ranges because of the distances they would need to travel from water to obtain forage. Ultimately, the allotments currently meeting Rangeland Health Standard 1 would see soil condition deteriorated until they no longer meet Standard 1 (or other standards). It is also likely that wild horses would expand outside their current HMAs as long as they were not restricted by adequate fencing. Under the No Action Alternative, additional trailing, trampling and compaction would occur at riparian zones and other water sources. Decreased percolation and water holding capacity and increased surface runoff from these water sources would result.

Vegetation

Alternative 1 (Proposed Action)
Over a period of 10 years, competition for forage and water between wild horses, wild life and livestock would be directly reduced. A reduced number of wild horses over this period of time within the Conger and Frisco HMAs would improve and/or sustain rangeland health and lower

utilization levels.

Indirect impacts from gathering to the low-range of the AML include reduced trailing by wild horses (less vegetation trampling/disturbance) as they travel to/from water and forage. Actual forage utilization by wild horses would also be reduced from heavy (61+% of annual year's growth) at the present time to moderate or less (<40-60%) within a 1-3 mile radius of the available water. Over the long term, reduced forage utilization would promote vegetation re-growth and provide for natural recovery of overgrazed plants. A reduced demand for forage would help improve the vigor of vegetation, allow for seedling establishment, increase ground cover, and thereby maintain a thriving natural ecological balance. The recovery from the most recent drought and the extended drought in the past 15 years would be allowed to continue and should show improved vegetative trend of key forage species, if precipitation remains near or above long-term average levels. Long-term rangeland health would continue to be met within and/or improve within the allotments as key forage and riparian areas would receive less use, especially during time of drought when wild horse are hardest on vegetation near water.

Reducing the wild horse population to within the AML would contribute to maintaining sufficient vegetation and litter within the HMAs to protect soil from erosion, meet plant physiological requirements, facilitate plant reproduction, and reduce potential for spread of noxious weeds.

This alternative would result in periodic gathers to remove excess wild horses from the Conger and Frisco HMAs. The first gathers would reduce the population for the research studies, and then between the 5-10 year period gathers would try to achieve then maintain the population within AML. For helicopter round-ups, direct impacts to vegetation would include short-term (1 to 10 days) disturbance of native vegetation immediately in and around temporary trap sites, and holding and handling facilities. For bait trapping, the direct impacts to vegetation would be longer (5-365 days) but would still be considered short term. There would be direct impacts to the vegetation immediately in and around temporary trap sites, and holding, sorting and animal handling facilities. Impacts created by vehicle traffic and hoof action of penned horses can be locally severe in the immediate vicinity of the corrals or holding facilities. Keeping the sites approximately ½ acre in size would minimize the disturbance area. Since most trap sites and holding facilities are re-used during recurring wild horse gather operations, any impacts would remain site specific and isolated in nature. In addition, most trap sites or holding facilities are selected to enable easy access by transportation vehicles and logistical support equipment and would therefore, generally be near or on roads, pullouts, water haul sites or other previously disturbed flat spots. These common practices would minimize the cumulative effects of these impacts.

The research part of the proposed action would not impact rangeland resources and vegetation directly. However, the data gained through the research would be used to improve the current management of wild horses, and are expected to lead to reduced impacts to other resources including vegetation.

Alternative 2 (Removal Only)
Impacts of the gather and removal would be similar to those described in Proposed Action.

Removal of excess wild horses would be beneficial to vegetative resources. The improved management of wild horses within these HMAs and others that would come from the research proposal would not occur at this time.

Alternative 3 (No Action)
Under the No Action Alternative, wild horses would continue to increase in population size beyond the capacity of the habitat to provide water and forage. Heavy and severe use of vegetation resources by wild horses would continue and increase, resulting in further degradation of plant communities, increased soil erosion, and susceptibility to invasive species. Downward trends in key perennial species would be expected in conjunction with reductions in ecological condition and soil stability. The vegetative functional groups (i.e. grass, shrubs, trees etc.) would be changed as grasses are over-used during critical growing seasons. Vegetation would also experience reduced production resulting in reduced forage availability to wildlife, livestock, and wild horses. Eventually, rangeland health would be reduced below a threshold that would be difficult to recover from.

Riparian/Wetland

Alternative 1 (Proposed Action)
The only direct impact to riparian/wetland areas that could result from the Proposed Action would be from possible use of riparian areas for employment of water trapping. Impacts from water trapping would include construction of a temporary trap around a water source that is designed to hold the horses until they can be transported or treated. Also, trampling of riparian vegetation could occur while the horses are in the trap. Helicopter trap sites and temporary holding facilities would not be constructed on riparian resources.

The Proposed Action would indirectly impact riparian wetland zones and water quality due to the decreased utilization by wild horses in these sensitive areas allowing for the possibility of riparian wetland areas to improve through natural processes. With a plan to only gather and remove 50-200 wild horses from each HMA in each successive gather operation, the improvements would occur incrementally as the wild horses are gathered over the next ten years until the low end of AML is reached. Under this alternative, native plant health, soils and would slowly improve. Any opportunity to make progress toward achieving and maintaining riparian areas in properly functioning condition would not be possible until reaching the lower end of AML.

Implementing the Proposed Action would slightly decrease current competition for water sources and alleviate pressures exerted on riparian habitat due to wild horses congregating around these sensitive areas. The functionality of riparian resources would improve in condition towards a more properly functioning condition (PFC) with the removal of excess wild horses.

Alternative 2 (Gather and Removal Only)
Impacts to the riparian wetland zones would be essentially the same under Alternative 2 as under the Proposed Action Alternative. Direct impacts to the riparian/wetlands would only occur during water or bait trapping direct at a riparian area. Indirect impacts would improve riparian/wetlands as excess wild horses are removed.

Alternative 3 (No Action)
The No Action Alternative would not have any direct impacts to riparian/wetland resources. Indirect impacts would result from continued and increased utilization on riparian vegetation as wild horse populations continue to increase. Wild horse population size would continue to increase in excess of the established AML. Riparian areas currently rated at Proper Functioning Condition (PFC), could experience downward trends caused by utilization of riparian vegetation and browse, and trampling by populations of wild horses in excess of AML. Riparian areas rated below PFC (Functional at Risk and Non-Functional) would likely not improve, and downward trends would continue. Wild horses have been identified through Proper Functioning Condition Assessments as a contributing factor in riparian areas within the Frisco HMA not being in PFC. Standard 2 in the Standards for Rangeland Health which states *"Riparian and wetland areas are in properly functioning condition…"* is not currently being met for riparian areas within the HMA.

Wild Horses

Alternatives 1 and 2
Over the past 35 years, various impacts to wild horses as a result of gather activities have been observed. Under the Proposed Action, potential impacts to wild horses would be both direct and indirect, occurring to both individual horses and the population as a whole.

The BLM has been conducting wild horse gathers since the mid-1970s. During this time, methods and procedures have been identified and refined to minimize stress and impacts to wild horses during gather implementation. The CAWP in Appendix B would be implemented to ensure a safe and humane gather occurs and would minimize potential stress and injury to wild horses.

In any given gather, gather-related mortality averages only about one half of one percent (0.5%), which is very low when handling wild animals. Approximately, another six-tenths of one percent (0.6%) of the captured animals, on average, are humanely euthanized due to pre-existing conditions and in accordance with BLM policy (GAO-09-77). These data affirm that the use of helicopters and motorized vehicles has proven to be a safe, humane, effective, and practical means for the gather and removal of excess wild horses (and burros) from the public lands. The BLM also avoids gathering wild horses by helicopter during the 6 weeks prior to and following the expected peak of the foaling season (i.e., from March 1 through June 30).

Individual, direct impacts to wild horses include the handling stress associated with the roundup, capture, sorting, handling, and transportation of the animals. The intensity of these impacts varies by individual, and is indicated by behaviors ranging from nervous agitation to physical distress. When being herded to trap site corrals by the helicopter, injuries sustained by wild horses may include bruises, scrapes, or cuts to feet, legs, face, or body from rocks, brush or tree limbs. Rarely, wild horses will encounter barbed wire fences and will receive wire cuts. These injuries are very rarely fatal and are treated on-site until a veterinarian can examine the animal and determine if additional treatment is indicated.

Other injuries may occur after a horse has been captured and is either within the trap site corral,

the temporary holding corral, during transport between facilities, or during sorting and handling. Occasionally, horses may sustain a spinal injury or a fractured limb but based on prior gather statistics, serious injuries requiring humane euthanasia occur in less than 1 horse per every 100 captured. Similar injuries could be sustained if wild horses were captured through bait and/or water trapping, as the animals still need to be sorted, aged, transported, and otherwise handled following their capture. These injuries can result from kicks and bites, or from collisions with corral panels or gates.

To minimize the potential for injuries from fighting, the animals are transported from the trap site to the temporary (or short-term) holding facility where they are sorted as quickly and safely as possible, then moved into large holding pens where they are provided with hay and water. On many gathers, no wild horses are injured or die. On some gathers, due to the temperament of the horses, they are not as calm and injures are more frequent. Overall, direct gather-related mortality averages less than 1%.

Indirect individual impacts are those which occur to individual wild horses after the initial event. These may include miscarriages in mares, increased social displacement, and conflict in studs. These impacts, like direct individual impacts, are known to occur intermittently during wild horse gather operations. An example of an indirect individual impact would be the brief 1-2 minute skirmish between older studs which ends when one stud retreats. Injuries typically involve a bite or kick with bruises which do not break the skin. Like direct individual impacts, the frequency of these impacts varies with the population and the individual. Observations following capture indicate the rate of miscarriage varies, but can occur in about 1 to 5% of the captured mares, particularly if the mares are in very thin body condition or in poor health.

A few foals may be orphaned during a gather. This can occur if the mare rejects the foal, the foal becomes separated from its mother and cannot be matched up following sorting, the mare dies or must be humanely euthanized during the gather, the foal is ill or weak and needs immediate care that requires removal from the mother, or the mother does not produce enough milk to support the foal. On occasion, foals are gathered that were previously orphaned on the range (prior to the gather) because the mother rejected it or died. These foals are usually in poor condition. Every effort is made to provide appropriate care to orphan foals. Veterinarians may administer electrolyte solutions or orphan foals may be fed milk replacer as needed to support their nutritional needs. Orphan foals may be placed in a foster home in order to receive additional care. Despite these efforts, some orphan foals may die or be humanely euthanized as an act of mercy if the prognosis for survival is very poor.

Through the capture and sorting process, wild horses are examined for health, injury and other defects. Decisions to humanely euthanize animals in field situations would be made in conformance with BLM policy. BLM Euthanasia Policy IM-2009-041 is used as a guide to determine if animals meet the criteria and should be euthanized (refer to CAWP, Appendix B). Animals that are euthanized for non-gather related reasons include those with old injuries (broken or deformed limbs) that cause lameness or prevent the animal from being able to maintain an acceptable body condition (greater than or equal to BCS 3); old animals that have serious dental abnormalities or severely worn teeth and are not expected to maintain an acceptable body condition, and wild horses that have serious physical defects such as club feet,

severe limb deformities, or sway back. Some of these conditions have a causal genetic component such that the animals should not be returned to the range; this prevents suffering and avoids amplifying the incidence of the deleterious gene in the wild population.

Wild horses not captured may be temporarily disturbed and moved into another area during the gather operation. With the exception of changes to herd demographics from removals, direct population impacts have proven to be temporary in nature with most, if not all, impacts disappearing within hours to several days of release. No observable effects associated with these impacts would be expected within one month of release, except for a heightened awareness of human presence.

It is not expected that genetic health would be affected by the Proposed Action. Available indications are that these populations contain high levels of genetic diversity at this time. More information about the genetic diversity in these populations will become available as a result of Alternatives 1 or 2. The AML range of 40 – 60 on the Frisco HMA and 40 – 80 on the Conger Mtn. HMA should provide for acceptable genetic diversity. If at any time in the future the genetic diversity in either HMA is determined to be relatively low, then a large number of other HMAs could be used as sources for fertile wild horses that could be transported into the HMA of concern.

By maintaining wild horse population size near the AML, there would be a lower density of wild horses across the HMA, reducing competition for resources and allowing the wild horses that remain to use their preferred habitat. Maintaining population size near the established AML would be expected to improve forage quantity and quality and promote healthy, self-sustaining populations of wild horses in a thriving natural ecological balance and multiple use relationship on the public lands in the area. Deterioration of the range associated with wild horse overpopulation would be reduced. Managing wild horse populations in balance with the available habitat and other multiple uses would lessen the potential for individual animals or the herd to be affected by drought, and would avoid or minimize the need for emergency gathers. All this would reduce stress to the animals and increase the success of these herds over the long-term.

Alternative 1 (Proposed Action)

Over the next 10 years, implementation of the Proposed Action would allow for data to be gather and analyzed that might better assist land managers and specialists make better decisions about use of gelding as a management tool for population growth suppression. No previous study of this type has examined the effect of gelding on the behavior of free-roaming wild horses, nor how they interact with intact wild stallions. In addition, the data collected from the Frisco HMA herd would provide necessary empirical data to build population dynamics models that may predict environmental factors which influence demographic parameters like survival and fertility rates. Recording such data will allow BLM to further its use of science to improve the BLM Wild Horse and Burro Program, in keeping with the BLMs science strategy (Kitchell et al. 2015).

Alternative 1 (Proposed Action) would gather up to 275 horses, of which 200 would be removed

to achieve a wild horse population to the level prescribed for the research study on the Conger HMA and gather up to 250 horses and remove 175 to achieve a wild horse population size to the level prescribed for the research study as a control population on the Frisco HMA. A ratio of 50%/50% male to female would be released back to the Conger HMA after selection of those to marked and fitted with radio collars/tags. In the Year 1 gather, mares and studs would be selected for release to maintain a diverse age structure, herd characteristics, and conformation (body type). During Year 2 of the study, horses within the Conger Mtn. HMA would be gathered and brought to the Delta Wild Horse Facility. Approximately 37 stallions would be treated by gelding, after which all gathered horses would be released back to the Conger Mtn. HMA.

The impact of radio collars and tags is very minimal. From March 2015 through March 2016 researchers at the U.S. Geological Survey conducted a preliminary study on captive wild horses and burro jennies to determine proper fit and wear of radio collars (Schoenecker et al. 2014). The condition of wild horses wearing radio collars was compared to non-collared controls and documented with photographs. In addition, both collared individuals and controls were observed for 80 minutes each week for 14 weeks in order to quantify any impact of the collar on their behavior and health. At the end of the study period (March 2016) the collars were removed. Preliminary analyses indicate that mares had almost no impact in terms of rubbing or wear from radio collars, and behavior of collared and uncollared mares did not differ (Schoenecker et al. 2016 *in prep*). There was no impact of radio tags on behavior or wear, either.

Recent research on non-lethal methods for managing population growth of free-roaming wild horses has focused largely on suppressing female fertility through contraception (Ballou et al. 2008, Killian et al. 2008, Turner et al. 2008, Gray et al. 2010, Ransom et al. 2011). Very few studies have been conducted on techniques for reducing male fertility. Nelson (1980) and Garrott and Siniff (1992) modeled potential efficacy of male-oriented contraception as a population management tool, and both studies agreed that while slowing growth, sterilizing only dominant males (i.e., harem-holding stallions) would result in only marginal reduction in female fertility rates. Eagle et al. (1993) and Asa (1999) tested this hypothesis on herd management areas (HMAs) where dominant males were vasectomized. Their findings agreed with modeling results from previous studies, and they also concluded that sterilizing only dominant males would not provide the desired reduction in population growth rate, assuming that the numbers of fertile females is not changed. While bands with vasectomized harem stallions tended to have fewer foals, breeding by bachelors and subordinate stallions meant that population growth still occurred. Garrott and Siniff (1992) concluded from their modeling that male sterilization would effectively suppress population growth only if a large proportion of males (>85%) could be sterilized, regardless of social order. However, sterilization of >85% of males in a population may have genetic consequences, reducing heterozygosity and increasing inbreeding coefficients, as it would potentially allow a very small group of males to dominate the breeding (as seen in equid reintroductions: Saltz et al. (2000), King unpublished data). Although such genetic consequences could be mitigated, the question of how >85% gelded males in a population would interact with intact stallions and mares and with their habitat is unknown. Garrott and Siniff's (1992) model predicts that gelding 50-80% of mature males in the population would result in reduced, but not halted, population growth. However, it is predicted that within 2 years of this treatment an entire foal crop of fertile males would become sexually mature, so the 85%

treatment would have to be repeated until foaling was suppressed. Even then after just a few years there would be an accumulation of fertile males coming to maturity. No previous study has directly focused on the individual or population-level effects of gelding males in a free-roaming horse population. A central and compelling reason to complete the proposed study is to inform BLM with data and associated analyses about these questions.

A literature search was conducted by a research scientist at Colorado State University to find scientific publications on the effect of gelding on horses and mammals in general. This search using the Web of Science and BioOne research search engines involved terms about gelding and castration in relation to behavior, as well as general effects. While over 220 hits were obtained for the various search terms, very few of the resulting papers were relevant to the question of the effect of gelding on the behavior of male horses in the wild. Despite livestock being managed by castrating males for centuries, there has been remarkably little research on castrates (Hart and Jones 1975, Jewell 1997). It is therefore unknown exactly what effect gelding an adult stallion and releasing him back in to a wild horse population will have on his behavior and that of the wider population, and can only be hypothesized from the scarce existing literature. Scientific data collected on the animals involved in this project would help to document the effects of maintaining geldings as a portion of a wild population.

Feral horses typically form bands composed of an adult male with 1 to 3 adult females and their immature offspring (Feist and McCullough 1976, Berger 1986, Roelle et al. 2010). In many populations subordinate ‘satellite’ stallions have been observed associating with the band, although the function of these males continues to be debated (see Feh 1999, and Linklater and Cameron 2000). Juvenile offspring of both sexes leave the band at sexual maturity (normally around two or three years of age (Berger 1986), but adult females may remain with the same band over a span of years. Group stability and cohesion is maintained through positive social interactions and agonistic behaviors among all members, and herding and reproductive behaviors from the stallion (Ransom and Cade 2009). Group movements and consortship of a stallion with mares is advertised to other males through the group stallion marking dung piles as they are encountered, and over-marking mare eliminations as they occur (King and Gurnell 2006). Quantifying these key wild horse behaviors is an important tool in understanding how the presence of a large number of gelded males may influence social structure in the population and ultimately how animals congregate and distribute themselves on the range.

In horses, males play a variety of roles during their lives (Deniston 1979): after dispersal from their natal band they generally live as bachelors with other young males, before associating with mares and developing their own breeding group as a harem stallion or satellite stallion. In any population of horses not all males will achieve harem stallion status, so all males do not have an equal chance of breeding (Asa 1999). Stallion behavior is thought to be related to androgen levels, with breeding stallions having higher androgen concentrations than bachelors (Angle et al. 1979, Chaudhuri and Ginsberg 1990). A bachelor with low libido had lower levels of androgens, and two year old bachelors had higher testosterone levels than two year olds with undescended testicles who remained with their natal band (Angle et al. 1979).

Dogs and cats are commonly neutered, and it is also common for them to continue to exhibit reproductive behaviors several years after castration (Dunbar 1975). Dogs, ferrets, hamsters, and

marmosets continued to show sexually motivated behaviors after castration, regardless of whether they had previous experience or not, although in beagles and ferrets there was a reduction in motivation post-operatively (Hart 1968, Dunbar 1975, Dixson 1993, Costantini et al. 2007, Vinke et al. 2008). Ungulates continued to show reproductive behaviors after castration, with goats and llamas continuing to respond to females even a year later in the case of goats, although mating time and the ejaculatory response was reduced (Hart and Jones 1975, Nickolmann et al. 2008).

Although libido and the ability to ejaculate tends to be gradually lost after castration (Thompson et al. 1980) some geldings continue to intromit (Rios and Houpt 1995). Stallion-like behavior in domestic horse geldings is relatively common (Smith 1974), being shown in 20-33% of cases whether the horse was castrated pre- or post-puberty (Line et al. 1985, Rios and Houpt 1995, Schumacher 2006). While some of these cases may be due to cryptorchidism or incomplete surgery, it appears that horses are less dependent on hormones than other mechanisms for the maintenance of sexual behavior (Smith 1974). Domestic geldings exhibiting masculine behavior had no difference in testosterone concentrations than other geldings (Line et al. 1985, Schumacher 2006), and in some instances the behavior appeared context dependent (Borsberry 1980, Pearce 1980). Domestic geldings had a significant prolactin response to sexual stimulation, but lacked the cortisol response present in stallions (Colborn et al. 1991).

No study has quantified the effect of castration on aggression in horses, with only one report noting that aggression was a problem in domestic horse geldings who also exhibited sexual behaviors (Rios and Houpt 1995). Castration is thought to increase survival as males are released from the cost of reproduction (Jewell 1997). In Soay sheep castrates survived longer than rams in the same cohort (Jewell 1997), and Misaki horse geldings lived longer than intact males (Kaseda et al. 1997, Khalil and Murakami 1999).

Wild horses are rarely gelded and released back into the wild, resulting in few studies that have investigated their behavior in free-roaming populations. In a pasture study of domestic horses, Van Dierendonk et al. (1995) found that social rank among geldings was directly correlated to the age at which the horse was castrated, suggesting that social experiences prior to sterilization may influence behavior afterward. Of the two geldings present in a study of semi-feral horses in England, one was dominant over the mares whereas a younger gelding was subordinate to older mares; stallions were only present in this population during a short breeding season (Tyler 1972). A study of domestic geldings in Iceland held in a large pasture with mares and sub-adults of both sexes, but no mature stallions, found that geldings and sub-adults formed associations amongsteach other that included interactions such as allo-grooming and play, and were defined by close proximity (Sigurjónsdóttir et al. 2003). These geldings and sub-adults tended to remain in a separate group from mares with foals, similar to castrated Soay sheep rams (*Ovis aries*) behaving like bachelors and grouping together, or remaining in their mother's group (Jewell 1997). In Japan, Kaseda and Khalil (1996) reported that young males dispersing from their natal harem and geldings moved to a different area than stallions and mares during the non-breeding season. Although the situation in Japan may be the equivalent of a bachelor group in natural populations, in Iceland this division between mares and the rest of the horses in the herd contradicts the dynamics typically observed in a population containing mature stallions. Sigurjónsdóttir et al. (2003) also noted that in the absence of a stallion, allo-grooming between

adult females increased drastically. Other interesting findings included increased social interaction among yearlings, display of stallion-like behaviors such as mounting by the adult females, and decreased association between females and their yearling offspring (Sigurjónsdóttir et al. 2003). In the same population in Iceland Van Dierendonck et al. (2004) concluded that the presence of geldings did not appear to affect the social behavior of mares or negatively influence parturition, mare-foal bonding, or subsequent maternal activities. Additionally, the welfare of broodmares and their foals was not affected by the presence of geldings in the herd. These findings are important because treated males in our study will be returned to the range in the presence of pregnant mares and mares with foals of the year.

These few studies may not reflect behavior of free-roaming wild horses in the western US, where ranges are much larger, intact stallions are present year-round, and population size and density may be highly variable. Additionally no study exists on the behavior of wild stallions pre- and post-castration, and what effects this will have on their group membership, home range, and habitat use. Studies on sterilization of harem stallions to control population growth all acknowledge that success is dependent on a stable group structure, as strong bonds between a stallion and mares reduce the probability of a mare mating an extra-group stallion (Nelson 1980, Garrott and Siniff 1992, Eagle et al. 1993, Asa 1999). It is therefore vital to know whether any gelded stallions remain with mares and maintain a stable group membership.

This study will examine not only behavioral changes, but also the effect of gelding treatment on home range and habitat use. Bands of horses tend to have distinct home ranges, varying in size depending on the habitat and varying by season, but always including a water source, forage, and places where horses can shelter from inclement weather or insects (King and Gurnell 2005). By comparison, bachelor groups tend to be more transient, and can potentially use areas of good forage further from water sources, as they are not constrained by the needs of lactating mares in a group. It is unknown whether gelded stallions will behave like group stallions, bachelors, or form a group of their own concentrating in prime habitat or in the vicinity of water sources due to reduced desire for mare acquisition, maintenance, and reproductive behaviors. This study is necessary to quantify such behaviors and habitat use patterns.

Several public comments received suggested that castrating a stallion will preclude it from roaming freely and that gelding wild horses will essentially create populations of “domestic horses” on public land, which will have no value for scientists or the public. Those suggestions are not accurate. Gelding wild horses does not change their status as wild horses under the act. In terms of whether geldings will continue to exhibit the free-roaming behavior that defines wild horses, BLM does expect that geldings would continue to roam unhindered in the HMA where this action would take place. The scientific study that is part of this proposed action is structured in a way that would allow for a quantitative testing of the hypothesis that there are differences in movement behaviors between gelded and intact stallions. Although there may be differences, BLM would be surprised if the results indicate that gelded animals cease to roam freely. In contrast to the statement that there is no utility to the advancement of science and to the public, at least one value of initiating this study would be to test for differences in movement patterns between geldings and intact stallions, which would allow for more quantitative measures of free-roaming behavior.

The BLM does anticipate that gelded individuals may exhibit some behavioral differences, when compared to their own pre-treatment behaviors, or when compared to other intact stallions; such differences would be quantified under the proposed action. There is absolutely no evidence that would suggest that a gelded wild horse would have its movements hindered or would become docile or obedient simply as a result of castration. While it may be that a gelded horse could have a different set of behavioral priorities than an intact stallion, the expectation is that geldings will choose to act upon their behavioral priorities in an unhindered way, just as is the case for an intact stallion. In this sense, a gelded male would be just as much 'wild' as defined by the act as any intact stallion, even if his patterns of movement differ from those of an intact stallion.

Wild horse movements may be motivated by a number of biological impulses, including the search for forage, water, and social companionship that is not of a sexual nature. As such, a gelded animal would still be expected to have a number of internal reasons for moving across a landscape and, therefore, exhibiting 'free-roaming' behavior.

Under the proposed action, reproductive stallions would still be a component of the population's age and sex structure. The question of whether or not a given gelding would or would not attempt to maintain a harem is not germane to population-level management. The scientific study proposed will evaluate the demographic and behavioral effects of having some geldings within the larger population of wild horses. Gelding a subset of stallions in the proposed action would not prevent other stallions and mares from continuing with the typical range of social behaviors for sexually active adults.

Some comments received state that gelded stallions would have drastically lower testosterone levels and that males would lose much of their masculine behavior, which is largely responsible for stallion behavior and also plays a role in the "free roaming" nature of wild horses. The notion that a sudden decrease in testosterone would eliminate free-roaming behavior relies on an unsupported implication that free roaming behavior means something more than unhindered movement. The proposed study would be able to answer the question of whether gelded wild stallions change their behaviors with respect to other wild horses. BLM does not at all expect that geldings would become in any way docile. BLM fully expects that geldings would remain feisty and unruly with respect to humans. Similar statements state that testosterone is partially responsible for the stallion behavior that maintains these intricate family bands and that introducing large numbers of castrated males would impact family structures within the herds. It should be noted that BLM has no legal, regulatory, or policy mandate to maintain any given ratio of sexually reproductive stallions to mares within any population of wild horses. Despite that, in the Conger HMA there would continue to be a number of intact stallions that one would expect continue to compete for available sexually mature mares. As such, BLM would expect that family structures to continue to be exhibited under the proposed action. The BLM also is not required to manage populations of wild horses in order to ensure that any given individual maintains its social standing within any given harem or band.

Castration (the surgical removal of the testicles, also called gelding or neutering) is a well-established surgical procedure for the sterilization of domestic and wild horses. The procedure is relatively straight forward, rarely leads to serious complications and seldom requires postoperative veterinary care. Gelding adult male horses results in reduced production of

testosterone which directly influences reproductive behaviors. Although 20-30% of domestic horses, whether castrated pre- or post-puberty, continued to show stallion-like behavior (Line et al. 1985), it is assumed that free roaming wild horse geldings would exhibit reduced aggressive and reproductive behaviors. Gelding of domestic horses most commonly takes place before or shortly after sexual maturity, and age-at-gelding can affect the degree to which stallion-like behavior is expressed later in life. The behavior of wild horse geldings in the presence of intact male horses has not been studied or well documented. This study is necessary to quantify such behaviors.

Though gelding is a common surgical procedure, minor complications are not uncommon after surgery, and it is not always possible to predict when postoperative complications would occur. Fortunately the most common complications are almost always self-limiting, resolving with time and exercise. Individual impacts to the stallions during and following the gelding process should be minimal and would mostly involve localized swelling and bleeding. A small amount of bleeding is normal and generally subsides quickly, within 2-4 hours following the procedure. Some localized swelling of the prepuce and scrotal area is normal and may begin between one to 5 days after the procedure. Swelling should be minimized through the daily movements (exercise) of the horse during travel to and from foraging and watering areas. Most cases of minor swelling should be back to normal within 5-7 days, more serious cases of moderate to severe swelling are also self-limiting and resolve with exercise after one to 2 weeks. Serious complications (eviscerations, anesthetic reaction, injuries during handling, etc.) that result in euthanasia or mortality during and following surgery are rare and vary according to the population of horses being treated. Normally one would expect serious complications in less than 5% of horses operated under general anesthesia, but in some populations these rates can be as high as 12% (Shoemaker 2004). These complications are generally noted within 3 or 4 hours of surgery but may occur any time within the first 7 days following surgery (Hunt 1989). If they occur they would be treated with surgical intervention when possible or euthanasia when there is a poor prognosis for recovery.

Another concern raised by some public comments was that geldings are unable to contribute to the genetic diversity of the herd. This is true, but it does not lead to an expectation that the Conger HMA would experience inbreeding. Existing levels of genetic diversity were high when last measured, and expectations are that heterozygosity levels are even higher now that the population has continued to grow exponentially. In addition, many of the stallions that are gelded would have already had a chance to breed, or have already passed on genetic material to their offspring. BLM is not obligated to ensure that all stallions born within a population have the chance to sire a foal and pass on genetic material. The herd in which the proposed action is to take place is not at immediate risk of catastrophic loss of genetic diversity, nor does the genetic diversity in this band represent unique genetic information. This action does not prevent BLM from augmenting genetic diversity in the treated herd in the future, if future genetic monitoring indicates that would be necessary. Any statement that the herd would not be viable is conjecture, and is not supported by the fact that the treated population would still have mares and intact stallions at all times.

The Conger HMA is located such that a small number of horses can enter the population from neighboring areas. As such, there is the potential for some additional genetic information to

continually enter this population. The BLM allows for the possibility that if future genetic testing indicates that there is a critically low genetic diversity in the Conger population and other populations that interact with it genetically, then future management of the Conger population could include genetic augmentation, by bringing in additional stallions, mares, or both.

Another public concern voiced was the opinion that there are less intrusive, more humane, and more sustainable forms of fertility control available to the BLM. In terms of fertility control options that are effective on male horses, other available methods such as the injection of GonaCon-Equine immunocontraceptive vaccine apparently require multiple handling occasions to achieve long-term infertility. Insofar as the law indicates that management should be at the minimum level necessary to achieve management objectives (CFR 4710.4), and if gelding some fraction of a managed population can reduce population growth rates by replacing breeding mares, it then follows that gelding some individuals can lead to a reduced number of handling occasions, which is consistent with legal guidelines. Similarly, PZP immunocontraception that is currently available for use in mares requires handling or darting every year, which is hard to construe as consistent with a minimum level of management. Any such management activities that require multiple capture operations represent management that could be interpreted as being more intrusive, less humane, and less sustainable than an activity that requires only one period of handling.

Alternative 2

Implementation of Alternative 2 would result in impacts from gather and removal activities similar to those described in proposed action. Alternative 2 would not involve any form of population growth suppression; stallions would not be gelded and mares would not receive population growth suppression. No research study would be implemented.

Alternative 3 (No Action)

Under the No Action Alternative, there would be no active management to control the population size within the established AML at this time. In the absence of a gather, wild horse populations would continue to grow at an average rate of 20% per year within the Frisco and Conger HMAs. Without a gather and removal now, the population would grow to 504 on the Frisco HMA and 590 on the Conger Mtn. HMA in four years' time.

Use by wild horses would continue to exceed the amount of forage allocated for their use. Competition between wildlife, livestock and wild horses for limited forage and water resources would continue. Damage to rangeland resources would continue or increase. Over time, the potential risks to the health of individual horses would increase, and the need for emergency removals to prevent their death from starvation or thirst would also increase. Over the long-term, the health and sustainability of any wild horse population is dependent upon achieving a thriving natural ecological balance and sustaining healthy rangelands. Allowing wild horses to die of dehydration or starvation would be inhumane and would be contrary to the WFRHBA which requires that excess wild horses be immediately removed. Allowing rangeland damage to continue to result from wild horse overpopulation would also be contrary to the WFRHBA which requires the BLM to "*protect the range from the deterioration associated with overpopulation*", "*remove excess animals from the range so as to achieve appropriate management levels*", and "*to preserve and maintain a thriving natural ecological balance and multiple-use relationship in*

that area."

Wildlife

Alternatives 1 and 2
Wildlife and wildlife habitat would be indirectly affected by the improvements in resource health from the removal of excess horses and research implementing the proposed action would reduce utilization on key forage species, improving the quantity and quality of forage available to wildlife and decreasing competition for water sources.

Activities such as using helicopters and roping can have short-term effects on wildlife due to increased noise (i.e. helicopters, roping) and increased human presence in the project area.

Bait and water trapping impacts would vary by individual wildlife species. The intensity of these impacts would be indicated by behaviors ranging from nervous agitation to physical distress. Temporary disturbance and/or displacement would occur to wildlife during set up of traps or the inability to escape from traps; however, since traps are monitored, it is very unlikely wildlife would become trapped. Minimal impacts are expected since trap sites and temporary holding facilities would be located primarily in already disturbed sites. If traps are located in areas of intact wildlife habitat, a wildlife inventory clearance would be required.

The use of radio collars/tags, gelding and other parts of the research portion of the proposed action would not impact wildlife.

Special Status Wildlife Species

Ferruginous hawks could be impacted temporarily and short term through increased human disturbance and noise. It is expected that after gather activities have ceased, ferruginous hawks would return to the area. Destruction of riparian habitat could lead to potential temporary impacts on Townsend big-eared bats foraging opportunities. Reduction of wild horse populations to within AML would decrease the impacts to these habitats.

Big Game

Direct impacts would consist primarily of disturbance and short-term displacement of big game by the low-flying helicopter, construction of temporary trap/holding facilities and water trapping locations. A reduction of the wild horse population would decrease competition for available forage, cover, space and water between big game and wild horses once the AML has been achieved.

Reducing wild horse populations to within AML would provide protection of riparian areas which are important for big game that seek cooler summer temperatures, valuable forage, water availability, and hiding cover as well as thermal cover in the winter. Mule deer and elk use riparian-wetland areas during fawn rearing because riparian vegetation provides a source of succulent grasses and forbs, which are nutritionally important nutrition during gestation and lactation. Lowland riparian areas provide a valuable source of water and succulent forage for

pronghorn.

Upland Game

The reduction of wild horse population to within AML would reduce impacts to upland game species. There would be less competition between wild horses and upland game species for sagebrush and grassland areas. These areas are nesting habitat for upland game species.

Migratory Birds and Raptors

The proposed action may include wild horse gather operations trapping during the migratory bird nesting season, typically April 1 – July 30, however the gather would likely have a low potential for disturbance to individual nesting birds and no potential for impact to migratory bird populations. Riparian areas provide important habitat requirements for migratory birds. These areas are used as riparian corridors and for breeding and wintering habitat. The proposed action should reduce overuse by horses in riparian areas, by reducing the number of wild horse that visit those areas on a daily basis.

The proposed action is not expected to impact the golden eagle nesting season, the gather would likely have a low potential for disturbance to individual golden eagle nesting birds. If disturbance did occur, it would be briefly while a helicopter flew by.

Alternative 3 (No Action)

Special Status Wildlife Species

Under the No Action Alternative impacts would continue between BLM special status species and wild horses; such as destruction and degradation of foraging habitat.

Big Game

Under the No Action Alternative, competition between wild horse and big game would continue and likely increase as the horse population increases. Key perennial species vigor and production would be reduced, thus limiting available forage to big game.

Upland Game

Under the No Action Alternative, wild horses would compete with upland game species for habitat that is suitable for nesting and foraging.

Migratory Birds and Raptors

The No Action Alternative would have no direct impact to migratory birds and golden eagles since the gather would not occur. Indirect impacts would be decreased forage and cover, which would cause a loss of habitat for some species of migratory birds.

Health and Safety
Members of the public can inadvertently wander into areas that put them in the path of wild horses that are being herded or handled during the gather operations, creating the potential for injury to the wild horses or burros and to the BLM employees and contractors conducting the gather and/or handling the horses as well as to the public themselves. Because these horses are wild animals, there is always the potential for injury when individuals get too close or inadvertently get in the way of gather activities.

While helicopters are highly maneuverable and the pilots are very skilled in their operation, unknown and unexpected obstacles in their path can impact their ability to react in time to avoid members of the public in their path. These same unknown and unexpected obstacles can impact the wild horses or burros being herded by the helicopter in that they may not be able to react and can be potentially harmed or caused to flee which can lead to injury and additional stress. When the helicopter is working close to the ground, the rotor wash of the helicopter is a safety concern by potentially causing loose vegetation, dirt, and other objects to fly through the air which can strike or land on anyone in close proximity as well as cause decreased vision.

Fleeing horses can go through wire fences, traverse unstable terrain, and go through areas that they normally don't travel in order to get away, all of which can lead them to injure people by striking or trampling them if they are in the animal's path.

Disturbances in and around the gather and holding corral have the potential to injure the government and contractor staff who are trying to sort, move and care for the horses and burros by causing them to be kicked, struck, and possibly trampled by the animals trying to flee. Such disturbances also have the potential for similar harm to the public themselves

These potential impacts would be minimized by safety measures described in Section 2.3 and the safe viewing areas set up to watch loading and sorting.

4.3 Cumulative Effects for All Alternatives

The NEPA regulations define cumulative impacts as impacts on the environment that result from the incremental impact of the Proposed Action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such actions (40 CFR 1508.7). Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. The cumulative impacts study area (CSA) for the purposes of evaluating cumulative impacts is the Conger and Frisco HMAs.

According to the 1994 BLM *Guidelines for Assessing and Documenting Cumulative Impacts*, the cumulative analysis should be focused on those issues and resource values identified during scoping that are of major importance. Accordingly, the issues of major importance to be analyzed are maintaining rangeland health and maintaining appropriate management level.

Past and Present Actions

Wild Horses

The Warm Springs Resource Area RMP/ROD Rangeland Program Summary (1987), designated the Conger Mountain HMA for the long-term management of wild horses. The HMA established in 1976 and identified in the "West Desert Wild Horse Capture Plan" (1977) are nearly identical in size and shape to the original herd areas identified in 1971. Management of wild horses within the HMA today is guided by the Warm Springs Resource Area RMP, 1987. AML was established as a population range of 40 – 80 on the Conger Mtn. HMA in 1987 through issuance of the Warm Springs Resource Area ROD.

The Pinyon Management Framework Plan (PMFP) (1983) and the Warm Springs Resource Area RMP/ROD Rangeland Program Summary (1987), identifies the Frisco HMA as suitable for wild horses, and allows for, "the removal of horses as required to maintain horse numbers at or below 1982 inventory levels, but not less than 1971 levels." (Pinyon MFP Wild Horse Amendment)(1983). The Frisco Herd Management Area Plan (2012) provides direction for management specific to the Frisco HMA and adjusted the AML to 30-60. The CCFO has records of six (6) wild horse gathers and removals that have occurred since 1971 within the Frisco HMA, resulting in the removal of approximately 463 wild horses from the area.

Congressional appropriations over the past ten years and most recently for the 2016 budget year prohibit the destruction of healthy animals that are removed or deemed to be excess. BLM policy is consistent with these appropriations provisions such that only sick, lame, or dangerous animals can be euthanized, and destruction is no longer used as a population control method. Nor does BLM sell excess wild horses for slaughter; rather BLM makes every effort to place excess wild horses with private citizens who can provide the animals with a good home.

Based on anecdotal observations from various BLM HMAs across the west, geldings released back to their home range: (1) tend to remain near where they were released (with adequate forage and water), (2) form small bachelor groups rather than join with a reproducing band, (3) maintain better body condition than the herd average because they are sexually inactive, (4) live longer in comparison to sexually active horses, and (5) were easy to recapture (many have been recaptured and released several times). (BLM Handbook H-4700-1) Those anecdotal observations were not based on a scientifically sound study design, and BLM will be able to update expectations about gelded wild stallions if the Preferred Alternative is selected.

Public interest in the welfare and management of wild horses continues to be very high. There are many different values pertaining to wild horse management from the public's perceptions. Some view wild horses as nuisance animals, while others strongly advocate management of wild horses as living symbols of the pioneer spirit.

Rangeland Health Standards

Through previous land use plan decisions, the BLM has allocated the available forage to wild horses, wildlife and domestic livestock. Other decisions, such as grazing permit renewals, have resulted in adjustments to livestock numbers and seasons of use and for implementation of grazing systems and the associated range improvements to promote rangeland health.

While the present livestock grazing system and efforts to manage the wild horse populations within AML has reduced past historic impacts, the current overpopulation of wild horses is continuing to contribute to areas of heavy vegetation utilization, trailing and trampling damage and is preventing the BLM from managing for rangeland health and a thriving natural ecological balance and multiple use relationship on the public lands in the area. Rangeland Health Assessments have been conducted within the Conger and Frisco HMAs for the associated livestock grazing allotments. Portions of the HMAs have been monitored over the past several years due to problems with drought, vegetation condition and the combined use of wild horses and domestic livestock. Adjustments have been made from these evaluations to the permitted use by livestock by way of season of use, livestock numbers, and grazing systems through the allotment evaluation and permit renewal processes.

The Proposed Action analyzed in this EA would result in the reduction in competition between wild horses and other users (i.e. native wildlife and domestic livestock) for the limited available forage and water resources. Direct improvements in soils and riparian condition would be expected in the short term and result in fewer multiple-use conflicts within and adjacent to the Conger and Frisco HMAs.

Over the long-term, improving the range would further benefit all users and the resources they depend on for forage and water.

Under the No Action (no removal) alternative, the current population of wild horses would not be reduced through the completion of a gather this year. Competition among wild horses, native wildlife and domestic livestock for limited resources would increase, and riparian conditions would continue to deteriorate. Over the long term, the health of wild horses and native wildlife would be expected to suffer as rangeland productivity further declines.

Wildlife

The greatest impacts to wildlife species in the area are the result of habitat degradation from drought, invasive weeds, livestock and wild horse grazing, OHV use and vegetation treatments on SITLA and private land. The proposed action would help to off-set these impacts by reducing the amount of forage utilized by wild horses.

4.4 Reasonably Foreseeable Future Actions

Future activities which could be expected to contribute to the cumulative impacts of implementing the Proposed Action or Alternatives within the next 10 years include continued mining exploration and development, oil and gas leasing, power line construction, solar, wind or other “green” energy production, livestock adjustments, treatment of invasive plants, noxious weeds, and pests, wild horse AML adjustments, wild horse population growth suppression, modification of wild horse sex ratios, non-reproducing wild horse herd components, herd augmentation, and wild horse removals.

Livestock grazing is expected to continue at similar stocking rates and utilization of the available

vegetation (forage) would also be expected to continue at similar levels. Rangeland Health Assessments would be planned to be completed in future years which could result in changes to livestock grazing systems such as changes to season of use, reduced or increased permitted use levels, or implementation of rotational grazing systems.

Any future actions that take place within the Conger and Frisco HMAs would be assessed through appropriate environmental documents in conformance with NEPA. For example, future mining plans of operation might require an EA or and EIS. Rangeland Health Assessments that adjust wild horse or livestock use might be accompanied by an EA, and future wild horse fertility treatment or gathers would be in conformance with this EA or new or amended EAs.

Livestock grazing is expected to continue at similar stocking rates and utilization of the available vegetation (forage) would also be expected to continue at similar levels. Continuing to graze livestock in a manner consistent with grazing permit terms and conditions would be expected to achieve or make significant progress towards achieving Rangeland Health Standards.

Past, present and future project with regards to properly planned vegetation and wildlife habitat improvement, invasive weed treatment, and range improvements are beneficial for wildlife. These projects generally ensure the quality of habitat and forage for wildlife species. Direct competition between wild horses, big game and other wildlife will continue to occur for perennial grasses, forbs, water and shelter. Wild horse populations have and would continue to influence the available forage for wildlife. As wild horse populations increase, the competition between wildlife and wild horses for limited resources would increase. As wild horses and wildlife are managed within the population goals and appropriate management levels (AML) this competition would be reduced. Abundance of small bird, mammal and reptile populations can be reduced because of habitat alteration. Wild horses can reduce the vegetation cover required to support adequate prey populations for raptor species.

Future actions that would affect vegetation in within the Conger and Frisco HMAs that are currently being developed and employed in surrounding areas within the Fillmore Field Office include the development of wind farms and pipelines, and the pursuance of the underground water resources within Snake Valley (Utah) by the Southern Nevada Water Authority for use within the Las Vegas, Nevada area. The loss of vegetation and water with the development of these activities would adversely affect the wild horse and native wildlife populations in the long-term through the loss of habitat.

While there is no anticipation for amendments to the WFRHBA, any amendments may change the management of wild horses on the public lands. The Act has been amended three times since 1971; therefore there is potential for amendment as a reasonably foreseeable future action.

4.5 Cumulative Impacts

Alternatives 1 and 2

The cumulative effects associated with the capture and removal of excess wild horses include gather-related mortality of less than 1% of the captured animals, about 5% per year associated with transportation, short term holding, adoption or sale with limitations and about 8% per year

associated with long-term holding. These rates are comparable to natural mortality on the range ranging from about 5-8% per year for foals (animals under age 1), about 5% per year for horses ages 1-15, and 5-100% for animals age 16 and older (Stephen Jenkins, 1996, Garrott and Taylor, 1990). In situations where forage and/or water are limited, mortality rates in the wild increase, with the greatest impact to young foals, nursing mares and older horses. Animals can experience lameness associated with trailing to/from water and forage, foals may be orphaned (left behind) if they cannot keep up with their mare, or animals may become too weak to travel. After suffering, often for an extended period, the animals may die. Before these conditions arise, the BLM generally removes the excess animals to prevent their suffering from dehydration or starvation.

While humane euthanasia and sale without limitation of healthy horses for which there is no adoption demand is authorized under the WFRHBA, Congress prohibited the use of appropriated funds between 1987 and 2004 and again in 2010 to present for this purpose.

The other cumulative effects which would be expected when incrementally adding either of the Action Alternatives to the cumulative study area would include continued improvement of upland and riparian vegetation conditions, which would in turn benefit permitted livestock, native wildlife, and wild horse population as forage (habitat) quality and quantity is improved over the current level. Benefits from a reduced wild horse population would include fewer animals competing for limited forage and water resources. Cumulatively, there should be more stable wild horse populations, healthier rangelands, healthier wild horses, and fewer multiple use conflicts in the area over the short and long-term. Over the next 15-20 years, continuing to manage wild horses within the established AML range would achieve a thriving natural ecological balance and multiple use relationship on public lands in the area.

Alternative 1 (Proposed Action)
In the future, application of population growth suppression techniques and adjustment in sex ratios to include some number of gelded males would be expected to slow total population growth rates, and to result in fewer gathers with less frequent disturbance to individual wild horses and the herd's social structure. However, return of wild horses back into an HMA could lead to decreased ability to effectively gather horses in the future as released horses learn to evade the helicopter.

Alternative 3 (No Action)
Under the No Action Alternative, the wild horse population within the Conger and Frisco HMAs combined could exceed 1000 in four years. Movement outside the HMAs would be expected as greater numbers of horses search for food and water for survival, thus impacting larger areas of public lands. Heavy to excessive utilization of the available forage would be expected and the water available for use could become increasingly limited. Eventually, ecological plant communities would be damaged to the extent that they would no longer be sustainable and the wild horse population would be expected to crash; this result could happen sooner than later under drought conditions.

Emergency removals could be expected in order to prevent individual animals from suffering or death as a result of insufficient forage and water. These emergency removals could occur as

early as 2016 with the current population levels, expected growth, and if there is persistent drought. During emergency conditions, competition for the available forage and water increases. This competition generally impacts the oldest and youngest horses as well as lactating mares first. These groups would experience substantial weight loss and diminished health, which could lead to their prolonged suffering and eventual death. If emergency actions are not taken, the overall population could be affected by severely skewed sex ratios towards stallions as they are generally the strongest and healthiest portion of the population. An altered age structure would also be expected.

Cumulative impacts of the no action alternative would result in foregoing the opportunity to improve rangeland health and to properly manage wild horses in balance with the available forage and water and other multiple uses. Attainment of site-specific vegetation management objectives and Standards for Rangeland Health would not be achieved. AML would not be achieved and BLM would forego the opportunity to collect the scientific data, which would include information about herd demography, effects of gelding, results from radio collar and GPS tags, fecal sampling, aerial survey enhancements, and population model development. All of those data would be necessary to re-evaluate AML levels in relationship to rangeland health standards, but would not be collected..

4.6 Monitoring and Mitigation Measures

The BLM Wild Horse Specialist, COR and PIs assigned to the gather would be responsible for ensuring all personnel abide by the CAWP (Appendix B).
Population research monitoring would be conducted by USGS/CSU in accordance with the protocol developed in the research proposal (Appendix A). Population inventories and vegetative monitoring (Rangeland Health, trend, utilization) would continue to be conducted as required by field office monitoring plans, BLM policy and the WFRHBA.

5.0 Consultation and Coordination

An annual single state-wide public hearing is held regarding the use of helicopters and motorized vehicles to capture wild horses (or burros) within the state of Utah. During the hearing, the public is given the opportunity to present new information and to voice any concerns or opinions regarding the use of these methods to capture wild horses (or burros). A hearing was held at the BLM Price Field Office, Price, Utah on December 8, 2015.

List of Preparers

The following list identifies the interdisciplinary team member's area of responsibility:

Name	Title	Area of Responsibility
Eric Reid	Assistant Field Manager	Project Lead/Wild Horses, Woodland/Forestry
Chad Hunter	Wild Horse and Burro Specialist	Wild Horses, ACECs, Environmental Justice, Farmlands (Prime or Unique), Floodplains, Invasive Species/Noxious Weeds, Rangeland Health Standards, Socio-Economics, Soils, Vegetation
James Priest	Wildlife Biologist	Wildlife, Migratory Birds, Threatened and Endangered and Special Status Species
Sheri Whitfield	Wildlife Biologist	Wildlife, Migratory Birds, Special Status Species
Stacey Whitman-Moore	Archeologist	Cultural Resources, Native American Religious Concerns
Jamie Palmer	Archeologist	Cultural Resources, Native American Religious Concerns
Teresa Frampton	Recreation Specialist	Wilderness, Visual Resources, Wild and Scenic Rivers, Lands/Access, ACECs, Recreation
David Jacobson	Recreation Specialist	Recreation, Wilderness, Visual Resources
Brian Taylor	Rangeland Management Specialist	Livestock Grazing, Standards for Rangeland Health, Vegetation
William Thompson	Rangeland Management Specialist	Farmlands (Prime or Unique), Riparian/Wetlands
Paul Caso	Rangeland Management Specialist	Soils, Floodplains, Air Quality, Water Quality, Water Rights
Adam Stephens	Rangeland Management Specialist	Air Quality, Greenhouse Gas Emissions, Hydrology, Water Quality, Riparian/Wetlands, Wild and Scenic Rivers
RB Probert	Weed Specialist	Invasive Species/Noxious Weeds
David Whitaker	Rangeland Management Specialist	Vegetation, Special Status Plant Species
Dan Fletcher	Assistant Field Manager	Special Status Plant Species
Gus Warr	Wild Horse and Burro Specialist	Wild Horses and Burros within the state of Utah

Alan Shepherd	Wild Horse and Burro Specialist	Wild Horses and Burros within the state of Nevada
Todd Leeds	Geologist	Geology/Mineral Resources, Wastes
Ed Ginouves	Geologist	Geology/Mineral Resources, Paleontology
Cindy Ledbetter	Environmental Coordinator	Greenhouse Gas Emissions, Environmental Justice, Paleontology, Socio-Economics
Gary Bishop	Assistant Fire Management Officer	Fire/Fuels Management
Melanie Mendenhall	Natural Resource Specialist	Fire/Fuels Management
Kyle Monroe	Engineering Technician	Property Boundary Evaluation
Michelle Campeau	Reality Specialist	Lands/Access
Glenn Pepper	Safety and Occupational Health Specialist	Wastes
Colby Peterson	Zone Forester	Woodlands/Forestry
Paul Griffin	Wild Horse and Burro Specialist	Population Statistical Modeling
Dr. Al Kane	APHIS Veterinarian	Animal Welfare
Dr. Kathryn Schoenecker	USGS	Research Proposal Lead
Dr. Sarah King	Colorado State University	Research Proposal Lead
Jared Bybee	Wild Horse and Burro Specialist	NEPA Compliance
Gina Ginouves	NEPA Specialist	NEPA Compliance

Public Involvement

Notification of the proposed action was listed on the ENBB and ePlanning (refer to section 1.7). A preliminary EA was made available for a 30-day public comment period. See Appendix G for a summary of the public comment period and comments received.

List of all Persons, Agencies and Organizations Consulted for Purposes of this EA

Name	Purpose & Authorities for Consultation or Coordination	Findings & Conclusions
Native American Tribes interested in projects within or interested in the state of Utah: Northwestern Band of Shoshoni Nation, Confederated tribes of the Goshute Reservation, Paiute Indian Tribe of Utah, Navajo	Consultation for undertaking, as required by the *Native American Graves Protection and Repatriation Act, the American Indian*	Identified tribes were notified October 1, 2015. The BLM has not received any letters expressing Native American concerns with the project.

Nation, Ute Indian Tribe of the Uintah and Ouray Reservation, Hopi Tribe, Southern Ute Tribe, Ute Mountain Ute Tribe, Pueblo of Zuni, Pueblo of Jemez, Shoshone Bannock Tribes, Eastern Shoshone Tribe	*Religious Freedom Act*, and various executive orders (e.g., Executive Order 13007)	
State of Utah, State and Institutional Trust Lands Administration, Renewable Resource Specialist	Consult with SITLA as the agency in control of state lands within the project area	
Millard County Commissioners	Consulted with Millard County	
Beaver County Commissioners	Consulted with Beaver County

PROTOCOL
IACUC
Colorado State University

Protocol # [redacted]
Date Printed: February 05, 2016

Protocol Title:	Evaluating the behavior and ecology of geldings among a breeding population
Protocol Type:	IACUC
Date Submitted:	10/15/2015
Approval Period:	12/21/2015-12/20/2018
Important Note:	This Print View may not reflect all comments and contingencies for approval. Please check the comments section of the online protocol.

* * * Personnel Information * * *

COLORADO STATE UNIVERSITY INSTITUTIONAL ANIMAL CARE AND USE COMMITTEE
ANIMAL USE APPLICATION

IACUC approval of this completed form is necessary prior to animals being obtained, housed or manipulated for research, testing or teaching purposes; performed at CSU or by CSU at other locations.

When you have completed all applicable sections of the protocol, you must also complete the certifications section and then click "Submit Form" link on the left-hand column.

All individuals listed on the protocol must have certified completion of the online CSU Animal Care and Use Training. Additionally, a "Training Record" should be uploaded in the Attachments section for the PI, Co-PI, and each person who will handle animals as a part of this study. Also, all individuals working with animals must be enrolled in the CSU Occupational Health and Safety Program (OHSP) via annual submission of a Risk Assessment Form to the OHSP.

Please contact an IACUC Coordinator if you have any questions.

* * * Species * * *

Species to be Used

Common Name	Horse			
Scientific Name	Horse			
Animal Sex	Male or Female			
Age Range	1	-	25	Year(s)
Weight Range	900	-	1500	lb(s)
Strain/Breed/Subline	Any strain			
Housing Location	Other			
	Wild animals on Conger Herd Management Area, Utah			
Room Number	N/A			
Maximum number of animals for three year project period	100			

USDA Pain Category (Choose all that will apply)

	Pain Category B	
X	Pain Category C	60
X	Pain Category D	40
	Pain Category E	

Pain Categories
Category B: Animals bred, conditioned or maintained for use in teaching, testing, or research, but not yet used for such purposes.
Category C: Animal use subjects them to no more than momentary or slight pain or distress and they do not receive pain-relieving drugs. Example : euthanasia prior to tissue collection; observation under normal conditions; positive rewards; routine injections (not Freund's adjuvant); tattooing; blood sampling.
Category D: Animal use subjects them to procedures where pain or distress is appropriately relieved with anesthetics, analgesics and/or tranquilizer drugs or other methods for relieving pain or distress which would otherwise be more than slight or momentary. Example: Needle biopsy non-survival or survival surgeries, terminal cardiac blood collection under terminal anesthesia; exposure of blood vessels for catheter implantation; induced infections or antibody production. PROCEDURES AT PAIN D REQUIRE VETERINARY CONSULTATION WITH THE UNIVERSITY VETERINARIAN OR DESIGNEE.
Category E: Animal use in which they must be subjected to unrelieved pain or distress for scientific reasons. Examples: toxicological or microbial testing or infectious disease research that requires continuation until severe clinical symptoms are evident or death occurs; application of noxious stimuli from which the animal cannot escape; prolonged restraint; use of paralyzing drugs for restraint of conscious animal; infliction of burns or trauma. PAIN E PROCEDURES REQUIRE CONSULTATION WITH THE UNIVERSITY VETERINARIAN OR DESIGNEE, AND MUST BE SCIENTIFICALLY JUSTIFIED IN THE PROTOCOL.

Source of Animals

Please indicate the source of the animals that will be used in the protocol. Be as specific as possible:
Outside Vendor (indicate whether purchased through LAR or by the investigator/department);
Transferred from another approved protocol (indicate protocol number);
Free-ranging Wildlife;
Faculty/Staff/Student-Owned ;
Client-Owned;
Other (please explain).

NOTE: If this is a study using Client Owned animals, you must provide a copy of the Informed Owner Consent Form along with approval from VMC Director in the Attachments section.

Free-ranging Wildlife managed by the Bureau of Land Management

---

* * * Are You Using? * * *

Please indicate if you propose to use any of the following so the IACUC may better assess your protocol.

1. Will you be using live animals for teaching? N

   What are the goals of the course(s) and who is the intended audience(s)?

   Please describe the preparation the students will have prior to handling live animals (e.g. lecture, demonstrations, anatomical model use, videos)

2. Will you be using euthanized animals for teaching purposes? N

   What will be the source of the animals (LAR or Vendor) and what is the disposal plan?

   What are the goals of the course(s) and who is the intended audience(s)?

3. Will you be collaborating with another institution(s)? Y

Institution(s)

Institution Name	Other
Other (please specify)	US Geological Survey
PHS Assurance #	
USDA Registration #	
Collaboration institution personnel	[redacted]

Briefly explain how the collaboration or subcontract is structured

Funding comes to USGS from BLM. [redacted] is an ecologist at USGS who is Affiliate Faculty at CSU and co-PI.

Please summarize if animals will be purchased by, housed, or have procedures performed by CSU personnel at this other institution.

No.

Institution Name	Other
Other (please specify)	Bureau of Land Management
PHS Assurance #	
USDA Registration #	
Collaboration institution personnel	

Briefly explain how the collaboration or subcontract is structured

BLM manages the horses in the wild and maintains the Delta Wild Horse Facility where surgery will take place.

Please summarize if animals will be purchased by, housed, or have procedures performed by CSU personnel at this other institution.

4. Will you be using biohazardous agents?

   a) Recombinant DNA (rDNA), human fluids or human tissues — N

   b) Infectious Agents? — N
   If you indicated "Yes" to 4a. or b. above, please provide IBC protocol "PARF" number, or indicate "Submitted" or "Submission Pending," as appropriate.

   c) Will this protocol involve the generation of new transgenic or knockout lines using rDNA? — N

   d) If using an infectious agent or toxin, is it on the USDA or CDC Select Agent List (see Select Agents for the two lists of agents)? — N

5. Will studies be performed under Good Laboratory, Good Clinical, or Good Manufacturing Practices (GLP/GCP/GMP)? Such studies are regulated by the Food and Drug Administration (FDA) or the Environmental Protection Agency (EPA). Please contact the CSU Quality Assurance Manager for additional review and approval of GLP/GCP/GMP documentation. — N
   If yes, please provide the name of the individual who will be the Study Monitor, and briefly describe how the project involves GLP/GCP/GMP or preliminary product testing.

6. Will you be using controlled drugs?
   Will controlled drugs (including HCG and Ketamine) be used? — Y
   If yes, list whose CSU "drug cabinet" will be accessed. — [redacted], DVM in Delta, Utah

7. Will carcinogenic or chemical substances that are hazardous to humans or animals be used? N

Toxic Agent(s)

8. Will you be using radiological agents N

Isotope(s)

9. Will this be a field study (i.e. conducted on free-living wild animals in their natural habitat)? In addition to IACUC approval, the investigator is responsible for obtaining all necessary federal/state or other government permits for wildlife studies. Y

Field Study or Wildlife Study

Are state, federal or local permit(s) required?	Y
For which species or circumstances are permits required?	Wild horse
Do any of these species carry a zoonotic disease (e.g., rabies, hantavirus, bird flu)?	Y
Do you need additional information on protective measures for personnel?	Y
Are any species involved in this research under endangered or protected categories? (State, Federal or IUCN listed species)	Y

Indicate which species and explain why these species must be used for research

Wild horses are protected under the Wild Horse and Burro Act (PL 92-195). The purpose of this research is to examine the effect of castrating a proportion of males on the behavior and ecology of the population.

Other pertinent information regarding wildlife or fish studies that may help the IACUC review this protocol

We have a signed proposal from BLM which forms the permit to conduct this research. BLM will complete a NEPA document and any necessary Environmental Assessments for gelding stallions.

If this research is conducted in the field, note the person responsible for, and storage location of records detailing sedation and/or other materials administered to the animals in this study

Person Responsible	[redacted], BLM
Storage Location	Fillmore Field Office, Utah

If voucher specimens are collected, list the institution(s) where they will be deposited.

N/A

*** Funding Sources ***

Funding Checklist

Funding - Grants/Contracts

Funding Administered By	Other
	NREL
Y	Has the proposal related to this protocol been submitted?

Sponsored Programs PASS# (if available)

Sponsor Grant ID#	
CSU Fund #	
Funded By	Bureau of Land Management (BLM)
Principal Investigator	[redacted]
Grant/Contract Title	Evaluating the behavior and ecology of geldings among a breeding population
Y	For Federal projects, are contents of this protocol the same as described in Federal proposal application?
N	Is this protocol under an Umbrella protocol?

Funding - Other

Dept. Funding

Other Funding

This protocol is funded (in whole or in part) with funding from an agency in the U.S. Department of Defense (DoD)? This includes direct grant/contract funding or subcontract work that is flow-through of funding from DoD. N

If DoD funding is involved, the PI will be responsible for obtaining approval from the DoD Animal Care and Use Research Office (ACURO) for all new protocols and amendments to existing protocols prior to initiation of the work/change to the protocol.

Check here if this project is self-funded (No aspect of this work will have charges to a sponsored project, departmental account, other CSU-related account associated with it.)

NOTE: Applicable Federal Grant Application, including competing renewals must be attached. Applicable investigator's brochure and sponsor's protocol must be attached for all industry sponsored clinical trials. You will be prompted for these in the Attachments section.

Has this protocol received other internal reviews (check all that apply):

Reviewed for CRC Funding	Yes	No X
Reviewed by VTH/Clinical Sciences Clinical Research Review Board:	Yes	No X
I assure that the activities described with in this document submitted for IACUC review are consistent with those described in any related grant, contract, or subcontract that has been submitted or awarded.	YES X	NO

*** Rationale ***

1. PROJECT INFORMATION

a) Protocol title

Evaluating the behavior and ecology of geldings among a breeding population

b) Application type

Note: If you are editing a previously approved protocol for an Amendment or Continuing Review, please leave the answer to the questions under b. below as they were in the originally approved protocol.

This project is a: (check only one)

X New project

4th year renewal (please enter number of protocol that you are renewing below)

If this is a 4th year renewal, please indicate the number of the protocol it is renewing.

2. LAY SUMMARY

a) What is the overall goal or purpose of this animal use?
Provide a brief description which would convey to a lay audience the purpose for the proposed use of animals. Use language understandable to a layperson. Avoid overly technical terms and define acronyms. The readability should be similar to a newspaper article. For example, the goal of a study could be expressed as follows: "Disease XYZ is a serious threat to the health of.... This project will seek to test the efficacy of treatment ABC." Or, "This project seeks to understand the cellular mechanisms that influence X through in vitro analysis utilizing tissues harvested from the proposed species Y."
Note: A section from your grant application using highly technical terms is not acceptable.

We aim to look at the effect of gelding (castrating) 75% of males in a wild horse population, to examine the effects at both an individual and population level. Wild horses in the United States became a federally protected species after the passage of the Wild Free-Roaming Horses and Burros Act in 1971. Many wild horse populations across the western United States are increasing at high rates and occupy habitats of limited forage availability and diversity. The Bureau of Land Management (BLM) is responsible for managing wild horses on public lands, and currently only have two options for managing population growth: removal of horses to holding facilities for public adoption or long-term maintenance, and suppression of female fertility. Neither of these options are perfect, as holding facilities are approaching capacity, and female immunocontraception requires repeat applications. There is therefore a need for further effective, nonlethal approaches to reducing wild horse population growth rates on public lands. While previous research efforts have focused on controlling female fertility, male sterilization through gelding (testicular removal) could provide this alternative approach. Gelded males will not be able to breed, but there is no research on how their presence will affect the rest of the population. This project will seek to evaluate the effects of gelding males on their behavior and spatial ecology, and to determine how it affects their health and short-term survival. Additionally we will examine these same effects in females within the population. Information on the impacts of gelding on the grouping and movements of wild horses, and whether geldings potentially have a greater impact to the habitat by overconcentrating near water sources or prime habitat will allow managers to make informed decisions about the suitability of this management option.

b) What will the impact of the use of live animals in this project be for human OR animal health, the advancement of knowledge, or the good of society?
Regulations and ethical standards require that procedures involving the use of animals in research or teaching be designed and performed with due consideration of their relevance to human or animal health, the advancement of knowledge or the good of society. Provide a brief description which would convey to a lay audience the impact the proposed research will have for one or more of the

above considerations. For example, "1 million people are estimated to contract disease XYZ each year. The proposed project will further the cause of developing effective treatments for the disease." Or "The cellular mechanisms X have previously been studied, but no studies have looked at aspect C of this mechanism. This study will advance the scientific understanding of X by exploring aspect C."
Note: Projects are not required to have application for human health to receive IACUC approval.

Wild horses are protected under Congress as they are considered cultural heritage, however their range is limited to where they were found when the Wild Free-Roaming Horses and Burros Act was passed in 1971. There are currently over 31,000 horses managed by the Bureau of Land Management (BLM) on public lands, with a potential for this number to increase by 20% every year. To control this growth the BLM removes horses from the range and places them in holding facilities where they are available for public adoption. Due to the low demand for these horses by the public there were 45,000 animals in holding facilities in 2012, maintenance of which consumes almost 60% of the BLM Wild Horse and Burro Program's budget. Little research has been conducted on the behavior and ecology of wild horses in the western United States over the past 20 years, despite a changing climate and different demands from the land. This study will impact animal health by providing a scientific understanding of the effects of gelding male horses in a free-roaming breeding population, and so inform its utility as a management tool for controlling horse population growth; it will advance knowledge of the behavior and ecology of wild horses, and be good for society in ensuring that cultural heritage remains.

3. JUSTIFICATION FOR USE OF ANIMALS

For parts a. and b. below, please answer "Yes" or "No" for each question.
There should be a Yes/No answer in all questions a)i. through a)vii. and b)i. through b)v.

a) Living animals are required for this project because:
(You should select either Y or N for each query.)

i)	Y		Complexity of the processes studied cannot be duplicated/modeled using in vitro models
ii)	Y		Not enough information known about processes being studied to design non-living models
iii)		N	Pre-clinical studies in living animals are necessary prior to human testing
iv)		N	This study requires tissue harvested from animals prior to in vitro testing
v)		N	Currently this is the best method to accomplish the required teaching
vi)	Y		Populations are being studied in natural or semi-natural environments
vii)	Y		Animal behavior is being studied

viii) Other (please specify):

b) This species has been selected because:
(You should select either Y or N for each query.)

i)	Y		Anatomy, physiology, behavior or agent susceptibility of species uniquely suited to the study
ii)		N	Lowest phylogenetic species providing adequate size, tissue, or anatomy for

proposed study

iii) N This species provides a particularly good model for the human or other animal disease or process

iv) N Previous studies which form the background for this project used this species

v) Y The objective of this study is to provide information about the target species

vi) Other (please specify):

4. JUSTIFICATION FOR NUMBER OF ANIMALS TO BE USED

The IACUC requires justification of proposed animal use numbers. A power calculation, confidence interval width, or an explanation why a power calculation is not feasible for this project should be provided. Complete one or more of the following (as appropriate) to justify the number of animals you will use (you may refer to Russ Lenth's U. Iowa stats website for statistical calculations). For experimental designs with multiple groups/treatments, it is suggested that a table of animal numbers per group be provided in the Attachments section. In addition make sure the animal numbers justified here agree with those mentioned in other sections of the application.

Answer N/A for any question (a-i) that is not applicable. There should be an answer or N/A in all boxes a-i.

a) This is an exploratory or pilot study. Describe how the proposed number of animals needed was determined. Note: A total of more than 12 animals indicates to the IACUC that the project may not be a pilot:

N/A

b) The group size was determined using a statistical package. Specify the statistical package used, effect size(s), estimate of variation used, and power level expected. (If multiple response variables are to be measured, the power calculation should be based on the most critical measures. When the objective is not to test but to estimate differences between mean or proportions, sample size may be justified based on confidence interval width criteria.):

N/A

c) This is a teaching protocol. Specify student-to-animal ratio, and explain how that was determined. There should be a clear correlation between the teaching objective and the number of animals per student:

N/A

d) This study involves tissue or cells harvested from animals for in vitro studies. Explain the number of animals requested for the amount of tissue needed to obtain a specified level of precision desired, or if an experiment involving the tissue samples will be conducted as part of this protocol, provide power calculations as described in b above. Cleary show the relationship between the number of animals requested and the number needed for the in vitro work:

N/A

e) This study involves breeding animals for later use in research, testing, or teaching. List the number of breeding males and females to be used/number of offspring produced each year, and describe how the animals are expected to be allocated to the subsequent experiment(s). If only a portion of the offspring will be usable in experiments, please indicate the number and reason for this:

N/A

f) This is a study of feral or wild animals where animals will be captured and released attempting to maximize sample size within logistical constraints. Describe and suggest a level of precision necessary to obtain useful information and the sample size required to obtain this precision:

The BLM has requested that we castrate 75% of males in the target population. Out of a population of 100 animals this will equate to about 40 males (we estimate around 37), as the others will be either female or juvenile males at the time of castration. Behavioral observations will be conducted on 16 focal male horses (8 of which will be castrated at the end of Year 1) and 4 focal female horses and their social associates (thus potentially including the majority of the 100 horses present at the HMA).

g) This is an observational, non-manipulative study in which animals will only be observed and animal numbers cannot be predicted. The animals will not be captured nor will their behavior be manipulated:

N/A

h) Sample size is government driven or agency mandated. Provide appropriate references documenting this requirement (e.g. product safety testing as mandated by FDA regulations):

See f.

i) Other. Please describe in detail:

N/A

---

* * * Procedures * * *

Surgical Procedure

Procedure Type:	Surgical Procedure		
Procedure Title:	Gelding		
Species:	Horse (Wild animals on Conger Herd Management Area, Utah)	**Pain/Distress Category:**	D
Approximate number of animals to be used in this procedure:			40
All D and E studies require date of consultation with the University Veterinarian; or, the name of other vet who was consulted:			IACUC mtg 11/17/15

Use Location (Campus)	BLM Delta Adoption Facility	**Building Name:**	Off-Campus
		Room Number:	NA

---

* * * Surgery Info * * *

Surgery Info

Specific room number where surgery is performed:	NA
Surgery Type:	S-Survival

ALSO NOTE: The Guide defines major surgery as one that penetrates and exposes a body cavity or produces substantial impairment of physical or physiological functions, and the USDA defines a major operative procedure as any surgical intervention that penetrates and exposes a body cavity or any procedure that produces permanent impairment of physical or physiological functions.

Will this project include Multiple Major Survival Surgery (MMSS)? N

PLEASE NOTE: If multiple major survival procedures are to be performed, you will be asked for specific justification in Project Overview section of this form.

Number of animals per year:

---

* * * Procedure Description * * *

Procedure Description

Procedure Description. Provide a brief description of how the procedure will be conducted. For blood/fluid collections include the route(s) of collection, volume, and frequency. For drug/compound dosing include route(s) of administration, volume, and frequency. For inoculations, include agent/vaccine information, route(s) of administration, volume, frequency, and dose. For procedures requiring administration of anesthesia, analgesia, provide the doses/route of administration; and for procedures requiring aseptic preparation, briefly describe animal, surgeon, and instrument preparation. Please DO NOT simply cut-and-paste from laboratory SOPs with superfluous or overly general information in them.

USGS or BLM will contract a clinical veterinarian to perform this procedure.

All animals will be sedated appropriately and then placed in lateral recumbency. A testicular block with a local anesthetic agent such as lidocaine or bupivacaine will also be done. The surgical site will be prepped using chlorhexidine scrub and the surgeon will wear sterile gloves to perform the castration procedure. Appropriate post-procedural medications will be given to the animals as well, e.g. tetanus shot, antibiotics, analgesics.

Please list any clinical effects or changes from normal health and behavior which may occur as a result of this procedure. This should include both short and longer-term effects of the procedure, as applicable.

The most common complications after gelding surgery are edema and excessive hemorrhage, with funiculitis, hydrocele, peritonitis, and penile damage reported as less common. Herniation and eventration has been reported, with incidences of these complications reduced if horses are checked for inguinal hernias prior to surgery. Behavior effects in a wild horse are not known.

Describe post procedure monitoring that will be performed. This should clearly indicate the frequency of monitoring, who will conduct it, and address the short- and longer-term complications that may result from the procedure.

Horses will be maintained in corrals for 24 to 72 hours after gelding, and then returned to the wild. In corrals they will be under veterinary supervision and visually checked at least twice a day. Once in the wild horses will be observed about once a week between April and August, and at least once a month through the rest of the year.

What criteria will be used to determine if animals exhibiting clinical or behavioral changes should be given rescue analgesia, other clinical treatments, or euthanasia. Please include any scoring system that will be used to determine when humane intervention will be triggered in the Attachments section or provide the scoring criteria below, as applicable.

Any males that have an inguinal hernia or are cryptorchid will not receive surgery, but be euthanized as per BLM IM 2009-063 (attached). If within the first 24 hours after surgery animals show excessive swelling and/or are refusing food and not moving they will be checked by a veterinarian and given rescue analgesia (Flunixin Meglumine) as necessary. Once released to the wild no further veterinary interventions are possible.

*** Surgeon Details ***

Surgeon Details

Surgeon Name

[redacted]

Y

Does the Surgeon have prior specific experience with this surgery on this species?

Describe the previous experience and/or training plan to assure surgical proficiency.

[redacted] has been practicing veterinary medicine for 14 years and has been contracted by the BLM for veterinary care for the wild horses at the Delta Wild Horse Facility in Utah throughout this time. At the facility he provides general veterinary care (disease prevention and treatments) for horses brought in from the range and performs gelding surgeries on the males that are sent to other facilities for adoption.

---

* * * Anesthetic Regimen * * *

Anesthetic Regimen

Note: Documentation of training is not required if you are using VMC or LAR services

Anesthetists

Anesthetist Name	[redacted]
Describe previous experience and training in anesthesia. (Note: If you are using VMC or LAR services type N/A here.)	Veterinarian contracted by the BLM for care of wild horses at the Delta Wild Horse Facility. Has anesthetized many wild horses to perform this gelding surgery.

Parameters monitored during surgery:

Respiratory rate and mucous membrane color.

Anesthetic Agents

Agent Name	Ketamine, Horse, 0.12-2.2 mg/kg
Dosage (in mg/kg if possible)	2.2 mg/kg
Route	Intravenous injection (IV)

Agent Name	Lidocaine
Dosage (in mg/kg if possible)	~10-20 mls
Route	Other intra-testicular

Agent Name	Bupivicaine
Dosage (in mg/kg if possible)	~10-20 mls
Route	Other intra-testicular

Paralytic Agents

Other premedications not already listed above

Agent Name	Xylazine
Dosage (in mg/kg if possible)	1.1 mg/kg
Route	Intravenous injection (IV)

Duration and Frequency of Administration

Once for sedation

---

* * * Perioperative Care * * *

Perioperative Care

Pre-emptive agents (analgesics given prior to procedure)

Intra-operative analgesics (local blocks;intracavity blocks).

Describe what parameters will be monitored during anesthesia/surgery to assure proper anesthesia.

Antibiotics or Anti-Microbials

Agent Name	**Penicillin G (procaine)**
Dosage (in mg/kg if possible)	22,000 units/kg
Route	**Intramuscular injection (IM)**

Duration and Frequency of Administration
Once

Post Operative Monitoring

Analgesic Agents

Agent Name	**Other** Flunixin Meglumine
Dosage (in mg/kg if possible)	2.2mg/kg
Route	**Intramuscular injection (IM)**

Duration and Frequency of Administration
Once

Recovery Location Building Name	Delta Wild Horse Facility, Delta, UT
Room Number	
Responsible Personnel	[redacted], [redacted] (BLM), [redacted] (BLM), [redacted], [redacted]
Parameters Monitored Note: Include any pain scale or scoring system as an attachment in attachments section.	We will monitor levels of swelling and whether the horse is eating post-surgery. Experience with horses will be used to assess pain, aided by the Horse Grimace Scale (attached) as necessary.
Monitoring Duration	24-72 hours
Monitoring Frequency	At least 2x day.

* * * Procedure Description * * *

Procedure Description

Procedure Description. Provide a brief description of how the procedure will be conducted. For blood/fluid collections include the route(s) of collection, volume, and frequency. For drug/compound dosing include route(s) of administration, volume, and frequency. For inoculations, include agent/vaccine information, route(s) of administration, volume, frequency, and dose. For procedures requiring administration of anesthesia, analgesia, provide the doses/route of administration; and for procedures requiring aseptic preparation, briefly describe animal, surgeon, and instrument preparation. Please DO NOT simply cut-and-paste from laboratory SOPs with superfluous or overly general information in them.

Behavioral observations do not require any surgical procedure. Horses will be observed through binoculars or a spotting scope from on foot or a vehicle, at a distance sufficient that the observer does not influence behavior. We will have 20 focal animals (16 males, 4 females) on which we will record maintenance and social behaviors, as well as their nearest neighbor. Behavior of social associates during observation sessions of the 20 focal animals will also be recorded, meaning that a large proportion of the whole population (up to 100 animals) may be observed.

Please list any clinical effects or changes from normal health and behavior which may occur as a result of this procedure. This should include both short and longer-term effects of the procedure, as applicable.

NA

Describe post procedure monitoring that will be performed. This should clearly indicate the frequency of monitoring, who will conduct it, and address the short- and longer-term complications that may result from the procedure.

Each of the 20 focal horses and their social associates will be observed for 16-18 hours a month between April and August each year. The rest of the year they will be visually checked at least once a month.

What criteria will be used to determine if animals exhibiting clinical or behavioral changes should be given rescue analgesia, other clinical treatments, or euthanasia. Please include any scoring system that will be used to determine when humane intervention will be triggered in the Attachments section or provide the scoring criteria below, as applicable.

Wild animals will not be given any veterinary care.

Herd Management

Procedure Type: Herd Management

Procedure Title: Gathering wild horses and handling them in captivity

Species: Horse (Wild animals on Conger Herd Management Area, Utah)

Pain/Distress Category: C

Approximate number of animals to be used in this procedure: 100

All D and E studies require date of consultation with the University Veterinarian; or, the name of other vet who was consulted:

Use Location (Campus) Field

Building Name: Off-Campus

Room Number: NA

---

* * * Procedure Description * * *

Procedure Description

Procedure Description. Provide a brief description of how the procedure will be conducted. For blood/fluid collections include the route(s) of collection, volume, and frequency. For drug/compound dosing include route(s) of administration, volume, and frequency. For inoculations, include agent/vaccine information, route(s) of administration, volume, frequency, and dose. For procedures requiring administration of anesthesia, analgesia, provide the doses/route of administration; and for procedures requiring aseptic preparation, briefly describe animal, surgeon, and instrument preparation. Please DO NOT simply cut-and-paste from laboratory SOPs with superfluous or overly general information in them.

Gathers will be conducted by the BLM following BLM IM 2013-059 and BLM Comprehensive Animal Welfare Program (CAWP) for wild horse and burro gathers (attached). Experienced BLM personnel will gather horse groups into corrals using appropriate methods, as indicated in the attachments (helicopters and/or bait traps). Bait traps will be used whenever feasible. Bait traps are described in the CAWP and IM 2013-059 (attached). Bait traps use food, mineral supplements, water, or a mare in heat as an attractants in to a temporary trap. The trap will be observed at least every 12 hours and water and food will be provided if animals are held for longer than 12 hours. When water is used as bait other water sources may be closed off to lure the horses to the trap, but will not be closed for a period that would adversely affect the wellbeing of other animals using the area.

Once caught, stallions and mares will be moved in to different corrals, with mare-foal pairs kept together. All horses will then be loaded in to BLM approved stock trailers for transport to the BLM Delta

Wild Horse Facility.

Please list any clinical effects or changes from normal health and behavior which may occur as a result of this procedure. This should include both short and longer-term effects of the procedure, as applicable.

Experienced BLM personnel will perform gathers and herd animals through the chute. Neither gathers nor moving animals through chutes should cause any pain to the animal, but being in close proximity to humans is not natural for wild horses and will cause stress. We will work to reduce the stress on study animals by working as quickly and efficiently as possible, and using quiet voices and low tones.

Following the BLM Comprehensive Animal Welfare Program (CAWP) for wild horse and burro gathers helicopters will remain at a distance from horse groups and move them as slowly as possible to corrals.

Describe post procedure monitoring that will be performed. This should clearly indicate the frequency of monitoring, who will conduct it, and address the short- and longer-term complications that may result from the procedure.

All horses will be carefully monitored during the gather by the PIs, BLM personnel, and an on-site veterinarian if a helicopter gather. When in corrals they will be monitored at least once every day by BLM personnel.

What criteria will be used to determine if animals exhibiting clinical or behavioral changes should be given rescue analgesia, other clinical treatments, or euthanasia. Please include any scoring system that will be used to determine when humane intervention will be triggered in the Attachments section or provide the scoring criteria below, as applicable.

Decision for euthanasia of horses will follow BLM IM 2009-041 (attached). As wild animals, horses other than those receiving surgery will not be given veterinary care.

* * * Alternative Search * * *

Alternatives Search

Federal regulations require that the fewest number of live animals necessary are used for research, testing, or teaching, and that investigators document that they have given all due consideration to reducing or eliminating the use of potentially painful or distressful procedures (Pain Category D or E). The USDA considers automated literature searches the most effective and efficient method for demonstrating compliance with the above requirements.

For ALL projects, regardless of pain categorization, please conduct a literature search utilizing terms that would allow you to demonstrate that the proposed research or other animal use is not unnecessarily duplicative of previously documented work. Please enter the appropriate Search Data (click the "Add" button) and answer Question 1 below.

If the proposed project involves procedures at Pain Categories D and/or E, documentation of a literature search which demonstrates that the fewest number of the lowest order of animals will be used to obtain valid results, and alternatives to EACH potentially painful/distressful procedure proposed have been sought. Therefore please enter the appropriate Search Data and answer Questions 2 & 3 below. See USDA Policies #11 and 12).

For assistance with alternatives searches, please consult the CSU Libraries IACUC Alternatives Search Help page, see the Alternatives to Painful or Distressful Procedures document (prepared by the University Veterinarian), or contact an IACUC Coordinator.

Click the "Add" button below to enter information pertinent to your search(es). Please then address question 1 and, as appropriate to the procedures to be conducted, address, questions 2-3.

Search Data

Search Range From: 1965
To: 2015
Search Date: 08/25/2015
Search Terms

Please provide the Keywords and the Boolean terms such as AND, OR used to relate keywords (e.g. term#1 [AND] term#2) for searches for each of the three components of the Alternatives Search indicated above:

gelding behavior; gelding ecology; gelding aggression; gelding sexual; gelding health; castrat* male behavior; fertility control male horse; male contraception horse; "chemical castration" horse; "chemical castrat*"; equine castration

Databases Searched (you must search at least 2 databases):

	Agricola Data Base		Google Scholar
	ALTBIB - Bibliography on Alternatives to Animal Testing		HSVMA Alternatives in Education Database
	SCIRUS		Lab Animal
	AnimAlt-ZEBET		Lab. Animals Journal
	ATLA (FRAME--Alternatives to Laboratory Animal Journal)		Medline / PubMed
X	BioOne (access from CSU Libraries website)		NORINA
	BIOSIS (Note: CSU Libraries does not subscribe to this database)		TOXLINE
	CAB Abstracts (access from CSU Libraries website)	X	Web of Science (access from CSU Libraries Website)
			Other, please specify:

1. **N** **Did the search reveal that your project is duplicative of previously documented work?**
   a) Please provide the number of hits and an overview of the results.

Searches for "gelding behavior" (109 hits), "gelding ecology" (5 hits), "gelding aggression" (9 hits), "gelding sexual" (37 hits),"fertility control male horse" (236 hits), "castrat* male behavior" (title only: 170 hits). Most of the papers that resulted were veterinary in nature, or dealt with management of captive domestic horses. There was only one paper that involved the behavior of geldings in the wild, or with stallions and breeding mares, and it did not describe their behavior or interactions beyond that they dispersed to a certain area and lived longer than intact stallions (Kaseda et al. 1997). The other most relevant papers dealt with keeping mares and geldings in groups in a pasture (Van Dierendonck and Spruit 2012, Van Dierendonck et al. 2004, 2009, Sigurjonsdotiir et al. 2003). Some papers referred to the continuation of libidinous behavior after castration (Borsberry 1980, Pearce 1980, Smith 1974). Papers on other species also attested to sexual behavior being observed after castration, however most of these papers were not relevant as the animals were castrated prior to puberty.

   b) If "Yes," please provide a list of the relevant citations and a discussion of how you determined that it is necessary to conduct the project anyway.

2. N **Did the search reveal any possible reductions or replacements that would allow the use of fewer animals or animals of a lower order?**

a) Please provide the number of hits and an overview of the results.

Searches for the terms "gelding behavior" (109 hits), "gelding ecology" (5 hits), "gelding aggression" (9 hits), "gelding sexual" (37 hits),"fertility control male horse" (236 hits), "castrat* male behavior" (title only: 170 hits), "male contraception horse" (34 hits), ""chemical castration" horse" (0 hits), "chemical castration horse" (9 hits), ""chemical sterilization" horse" (0 hits), ""chemical castrat*"" (146 hits). Although some of these results described the effects of castration in rodents (e.g., Achiraman et al. 2014, Constantini et al. 2007, Hume and Wynne-Edwards 2005, Turner et al. 1980) or primates (e.g. Dixson 1993) their results were not relevant to this study as the species had different social systems. Furthermore our sample size is determined by the Bureau of Land Management and as our aim is to examine the effect of gelding on a wild horse population we cannot use animals of a lower order.

b) If "Yes," please provide a list of the relevant citations and a discussion of how you determined that it is necessary to conduct the project as proposed.

3. N **Did the search reveal any possible refinements that would allow the use of alternative procedures to those that will potentially cause pain and/or distress for the animals (Protocols utilizing procedures at pain category D and/or E)?**

a) Please provide the number of hits and an overview of the results.

We searched for the terms "fertility control male horse" (236 hits), "male contraception horse" (34 results), ""chemical castration" horse" (0 hits), "chemical castration horse" (9 results), ""chemical sterilization" horse" (0 results), ""chemical castrat*"" (146 results) in order to see if there were any options to surgical castration of males. Only one paper described a potential drug that could be used for chemical castration of stallions (Pozor et al. 2013), but the effects were reversible within about 71 days; we need permanent sterilization or a drug that would not need to be re-applied. Most of the chemical castration papers were about human sex offenders, with the remainder discussing chemical castration in other species. These papers were not applicable to our study as either the animals were chemically castrated pre-puberty, or else the paper did not state whether sterility was permanent or would need re-application. Furthermore we cannot use untested drugs on wild horses without checking their suitability first, which is out of the scope of this study. Three papers discussed vasectomies in horses: in zoo animals (Silber et al. 2013), in wild horses (Eagle et al. 1993), and a model of the effects in wild horses (Garrott and Siniff 1992). Prior to proposing this study we discussed the use of vasectomies with the Bureau of Land Management, but it was decided to focus this study on testicular removal rather than vasectomy.

b) If "Yes," please provide a list of the relevant citations and a discussion of how you determined that it is necessary to conduct the project as proposed.

Teaching Protocols

1. If this is a teaching protocol, please specify why there are no alternatives to using live animals.

Protocols Involving Unrelieved Pain or Distress

1. For Pain Category E procedures, explain why drugs or other ameliorative treatments cannot be used to fully alleviate pain/distress. Please provide citations to the relevant literature.

Other Means of Determining Non-Duplication and Alternatives

The Animal Welfare Act allows other means of determining whether your project is duplicative AND whether it can be refined to decrease the animal number or order, AND to determine if alternatives to a potentially painful/distressful procedure can be used. For example, under some circumstances, colloquia, subject expert consultants, or other sources may provide relevant and up-to-date information regarding alternatives. When other sources are the primary means of considering alternatives, sufficient documentation, such as the consultant's name and qualifications and the date and content of the consult should be provided. If you used an alternative search strategy, provide information on the strategy, methods, sources, and relevant findings.

---

* * * Project Overview * * *

Project Overview

Provide a clear and concise sequential description of the procedures the animals will undergo. The description should include information on the experimental groups and the study endpoints. It should allow the reader to see the timing and relationship of all procedures that will be conducted with the animals. For lengthy or complex experiments with many groups and/or procedures, a table or flowchart showing the experimental manipulations by group should also be uploaded into the Attachments section. A response here is required.

January or February 2016 - gather horses and put radio collars on 30 male and 30 female horses (covered under FORT IACUC 2015-10 and the Inter-Institutional Agreement (IIA) with CSU, attached).

April to August 2016 - collect pre-treatment data on aggression, affiliative behavior, reproductive behavior, and band membership and fidelity of focal animals and their social group. Experimental groups will consist of: 4 adult females and their social groups, plus 16 adult male bachelors (n=8) and harem stallions (n=8) and their social groups. Focal individuals will include representatives of adult age groups and stallion social status present.

Fall 2016 – gather and treat animals (timing is dependent on BLM's gather schedule). All horses at Conger HMA will be gathered (as far as possible) and transported to the Delta BLM facility in BLM approved transport. Gathers and transport will follow BLM IM 2013-059 and follow their animal welfare standards (see attached). We will coordinate with the BLM and contract a veterinarian to perform the gelding surgery. Males for gelding will be selected randomly, blocked by age and social status, with a total of 75% of adult (≥3 years old) males receiving surgery (~37 horses). Animals with a Henneke body condition score of ≤3, and/or over the age of 18 (estimated by tooth wear) will not be gelded. Of the 16 focal stallions for behavioral observations, 8 will be gelded (4 bachelors and 4 harem stallions). Twenty four to 72 hours after gelding, depending on veterinary advice, the wild horses will be returned to the HMA and released. Exercise after gelding is recommended to reduce edema at the surgery site (Searle et al. 1999), and release of all horses at the same time will ensure that time in captivity is consistent between treatment and control animals. All collared horses will be visually checked at least once per month during the winter, with as many of the other geldings found as possible.

April to August 2017- collect post-treatment data on behavioral variables using the same focal individuals and whatever group they are in, whether or not they remain with the same group after gelding. Continue to visually observe radio marked individuals by locating them ≥1x/month to check collars and survival, presence of foals, and other population parameters.

April to August 2018- collect post-treatment data on behavioral variables using the same focal individuals and whatever group they are in. Continue to visually observe radio marked individuals by locating them ≥1x/month to check collars and survival, presence of foals, and other population parameters.

April to August 2019- collect post-treatment data on behavioral variables using the same focal individuals and whatever group they are in. Continue to visually observe radio marked individuals by locating them ≥1x/month to check collars and survival, presence of foals, and other population parameters. Check that collars drop off as programmed at the end of 2019, otherwise bait trap to

remove collars that fail. In 2020 initiate data analyses and conduct manuscript preparation.

Multiple Major Survival Surgery(MMSS) Description:

Describe why it is necessary to perform multiple major surgical procedures on the same animal.

---

* * * Husbandry * * *

Animal Care/Husbandry

Emergency Contact Information

List all individuals/phone numbers that are to be notified by veterinary staff or others in the event of an emergency:

[redacted] (CSU) - [redacted] [USGS/CSU]
[redacted] (BLM) - [redacted]
[redacted] (BLM) - [redacted]

Will Lab Animal Resources provide the daily care **N**

If "No," specify who will provide the daily care:

Animals are wild, so will not receive daily care. When at the Delta Wild Horse Facility they will be under the daily care of the facility manager.

If "No," justify why LAR will not be providing animal care:

Animals will be located in Utah.

What veterinarian will provide medical care to animals? **Other**

If "Other" specify who:

[redacted] DVM

Contact information:

[redacted] Veterinarian Services, [redacted] or [redacted] (cell)

If "Other" justify why LAR will not be providing medical care:

Animals will be located in Utah

Location of medical records (indicate building/room or other applicable information):

Medical records will be maintained by BLM at the Fillmore Field Office in Fillmore, Utah.

Special Husbandry or Care

List any special or unusual requirements for care of the animals and who will provide this care (e.g. special diet, altered light cycle, variation from standard enrichment, etc.):

N/A

Non-standard Experimental Requirements (Procedures requiring Exemptions from the Guide).

Social Housing

If you are using a social species there are mandatory housing requirements. CSU considers social housing to include compatible housing with conspecifics, as well as housing in the same secondary containment with visual, auditory, olfactory or tactile contact with conspecifics. See the "Policy on Social Management of Animals" on the IACUC Policies and Guidelines Page.

Please indicate which of the following is true:

1. Animals will be provided with social housing (unless an animal has individual incompatibility or vet care concerns, or due to cohort attrition).

X 2. Animals will not be housed at CSU.

3. Animals will be housed singly because that is appropriate for this species (including hamsters, rabbits, male mice, tom cats, and livestock in stalls).

4. Animals will be housed singly because such housing is necessary for research, testing or teaching goals.

If you will be housing animals singly for research, testing or teaching purposes (#4 above), you must provide a written justification which indicates the experimental constraints that make the housing necessary:

Food or Fluid restriction (other than up to 12 hours prior to surgery/general anesthesia) X None

Food or Fluid restriction

Species	Food Restriction	Length of Restriction	Fluid Restriction	Length of Restriction	Reason for Restriction
Horse (Wild animals on Conger Herd Management Area, Utah)					

Description

Restraint of Conscious Animals (other than momentary restraint for routine procedrues, e.g. blood collections, injections, and such) X None

Restraint of Conscious Animals

Species	Type restraint (manual, commercial, manual and commercial)	Please describe Acclimation to restraint	Length of restraint
Horse (Wild animals on Conger Herd Management Area, Utah)			

Description

Non-standard housing requirements X None

Non-standard housing requirements

Species	Cage/Pen size	Cage Sanitation Interval	Wire-bottom rodent cages or grids	Animals outside dedicated animal housing for greater than 12 hours	Exemption from exercise (dogs only)
Horse (Wild animals on Conger Herd Management Area, Utah)					

Description

*** * * Disposition of Animals * * ***

Please provide the information requested below regarding what will happen to animals at study end. (Check all that apply)

	Animals will be adopted (Note, PI is required to follow the IACUC "Policy on Animal Adoptions" which is located on the page IACUC Policies and Guidelines Page.
	Sold at auction (hoof stock only)
X	Released into home territory (wildlife studies)
	Returned to client
	Transferred to other studies (please specify below)
	Animals will be euthanized (Please add method below)

If using CO_2 as the method of euthanasia for mice and rats, please be aware that the IACUC requires use of the "Directions for CO_2 Euthanasia of Rodents" (available on the IACUC Policies and Guidelines Page) unless the protocol provides scientific justification why that procedure cannot be used.

Euthanasia Method

Please briefly describe what will happen with the animals at the conclusion of the study in the text box below:

*** Guidelines ***

Guidelines

The CSU IACUC Policies and Guidelines page can assist you and your staff in the protocol development and animal study process.

*** Certifications ***

I understand that changes in the approved protocol must be submitted in writing to the IACUC as a protocol amendment and approved by the IACUC prior to implementation. Such changes include, but are not limited to: species, animal numbers, animal-related procedures, animal restraint, food/water deprivation, euthanasia, PI, research staff, and the like. Minor changes can be reviewed by the IACUC via the designated member review process throughout the month; significant changes (e.g. a large increase in animal numbers, adding an invasive procedure) usually require a new protocol be submitted for review by the IACUC at its next regularly scheduled meeting.

Please contact an IACUC Coordinator if you have any questions about preparing new protocol applications, amendment requests, or continuing reviews.

Certification Test

By submitting this protocol to the CSU Institutional Animal Care and Use Committee (IACUC), the Principal Investigator certifies the following:

1) I assure that myself and all students, staff, and faculty on this project are familiar with the Animal Welfare Act (AWA) and AWA Regulations and the Public Health Service (PHS) Policy on Humane Care and Use of Laboratory Animals, the Guide for the Care and Use of Laboratory Animals, and the Guide for the Care and Use of Agricultural Animals in Research and Teaching, as applicable, and all recognize their responsibility in strictly adhering to approved protocols.

2) I assure that all individuals listed on this project are qualified through education and/or training to conduct procedures involving animals under this proposal and have taken the online CSU Animal Care and Use Training, which includes information on the regulatory responsibilities of the institution, the IACUC, and investigators, as well as the concepts of research or testing methods that limit the use of animals or minimize distress, and the methods for reporting animal welfare concerns. Additionally, as applicable to their work with animals, all individuals on the protocol have received training in the biology, handling, and care of the species to be used; aseptic surgical methods and techniques; and the proper use of anesthetics, analgesics, and tranquilizers.

3) I assure that all procedures will be conducted in accordance with all applicable Colorado State University IACUC policies as well as Occupational and Biosafety requirements, including those pertaining to the use of personal protective equipment.

4) I assure that all individuals working on this proposed protocol are participating in the Occupational Health and Safety Program (OHSP).

5) I assure that ANY change in the care and use of animals involved in this protocol will be promptly forwarded to the IACUC for review. Such changes will not be implemented until approval is obtained from the IACUC. Animals will not be transferred between investigators without prior approval.

6) I assure that I have reviewed the pertinent scientific literature and the sources and/or databases and have found no valid alternative to any procedures described herein which may cause more than momentary or slight pain, distress, or generalized discomfort to animals, whether it is relieved or not.

7) I assure that every effort has been made to minimize the number of animals used and reduce the amount of pain, distress, and/or discomfort these animals must experience.

8) I assure that the activities described in this document submitted for IACUC review are consistent with those described in any related grant, contract, or subcontract that has been submitted or awarded.

9) I assure that the information contained in this application for animal use is accurate to the best of my knowledge.

10) I understand that this application and/or my animal use privileges may be revoked by the IACUC if I violate any of the aforementioned assurance statements.

X The Principal Investigator has read and agrees to abide by the above assurances

STANDARDS

Standard Definitions
Major Standard: Impacts the health or welfare of WH&Bs. Relates to an alterable equipment or facility standard or procedure. Appropriate wording is "must," "unacceptable," "prohibited."
Minor Standard: unlikely to affect WH&Bs health or welfare or involves an uncontrollable situation. Appropriate wording is "should."
Lead COR = Lead Contracting Officer's Representative
COR = Contracting Officer's Representative
PI = Project Inspector
WH&Bs = Wild horses and burros

FACILITY DESIGN

A. Trap Site and Temporary Holding Facility
   1. The trap site and temporary holding facility must be constructed of stout materials and must be maintained in proper working condition, including gates that swing freely and latch or tie easily. (**major**)
   2. The trap site should be moved close to WH&B locations whenever possible to minimize the distance the animals need to travel.(minor)
   3. If jute is hung on the fence posts of an existing wire fence in the trap wing, the wire should be either be rolled up or let down for the entire length of the jute in such a way that minimizes the possibility of entanglement by WH&Bs unless otherwise approved by the Lead COR/COR/PI. (minor)
   4. Fence panels in pens and alleys must be not less than 6 feet high for horses, 5 feet high for burros, and the bottom rail must not be more than 12 inches from ground level. (**major**)
   5. The temporary holding facility must have a sufficient number of pens available to sort WH&Bs according to gender, age, number, temperament, or physical condition. (**major**)
      a. All pens must be assembled with capability for expansion. (**major**)
      b. Alternate pens must be made available for the following: (**major**)
         1) WH&Bs that are weak or debilitated
         2) Mares/jennies with dependent foals
      c. WH&Bs in pens at the temporary holding facility should be maintained at a proper stocking density such that when at rest all WH&Bs occupy no more than half the pen area. (minor)
   6. An appropriate chute designed for restraining WH&Bs must be available for necessary procedures at the temporary holding facility. This does not apply to bait trapping operations unless directed by the Lead COR/COR/PI. (**major**)
   7. There must be no holes, gaps or openings, protruding surfaces, or sharp edges present in fence panels or other structures that may cause escape or possible injury. (**major**)
   8. Padding must be installed on the overhead bars of all gates and chutes used in single file alleys. (**major**)
   9. Hinged, self-latching gates must be used in all pens and alleys except for entry gates into the trap, which may be secured with tie ropes. (**major**)
   10. Finger gates (one-way funnel gates) used in bait trapping must be constructed of

materials approved by the Lead COR/COR/PI. Finger gates must not be constructed of materials that have sharp ends that may cause injuries to WH&Bs, such as "T" posts, sharpened willows, etc. (**major**)

11. Water must be provided at a minimum rate of ten gallons per 1000 pound animal per day, adjusted accordingly for larger or smaller horses, burros and foals, and environmental conditions, with each trough placed in a separate location of the pen (i.e. troughs at opposite ends of the pen). Water must be refilled at least every morning and evening. (**major**)
12. The design of pens at the trap site and temporary holding facility should be constructed with rounded corners. (minor)
13. All gates and panels in the animal holding and handling pens and alleys of the trap site must be covered with materials such as plywood, snow fence, tarps, burlap, etc. approximately 48" in height to provide a visual barrier for the animals. All materials must be secured in place.(**major**)

These guidelines apply:

a. For exterior fences, material covering panels and gates must extend from the top of the panel or gate toward the ground.(**major**)
b. For alleys and small internal handling pens, material covering panels and gates should extend from no more than 12 inches below the top of the panel or gate toward the ground to facilitate visibility of animals and the use of flags and paddles during sorting. (minor)
c. The initial capture pen may be left uncovered as necessary to encourage animals to enter the first pen of the trap. (minor)

14. Non-essential personnel and equipment must be located to minimize disturbance of WH&Bs. (**major**)
15. Trash, debris, and reflective or noisy objects should be eliminated from the trap site and temporary holding facility. (minor)

B. Loading and Unloading Areas

1. Facilities in areas for loading and unloading WH&Bs at the trap site or temporary holding facility must be maintained in a safe and proper working condition, including gates that swing freely and latch or tie easily. (**major**)
2. The side panels of the loading chute must be a minimum of 6 feet high and fully covered with materials such as plywood or metal without holes that may cause injury. (**major**)
3. There must be no holes, gaps or openings, protruding surfaces, or sharp edges present in fence panels or other structures that may cause escape or possible injury. (**major**)
4. All gates and doors must open and close easily and latch securely. (**major**)

5. Loading and unloading ramps must have a non-slip surface and be maintained in a safe and proper working condition to prevent slips and falls. Examples of non-slip flooring would include, but not be limited to, rubber mats, sand, shavings, and steel reinforcement rods built into ramp. There must be no holes in the flooring or items that can cause an animal to trip. (**major**)
6. Trailers must be properly aligned with loading and unloading chutes and panels such that no gaps exist between the chute/panel and floor or sides of the trailer creating a situation where a WH&B could injure itself. (**major**)
7. Stock trailers should be positioned for loading or unloading such that there is no more than 12" clearance between the ground and floor of the trailer for burros and 18" for horses. (minor)

I. CAPTURE TECHNIQUE

A. Capture Techniques

1. WH&Bs gathered on a routine basis for removal or return to range must be captured by the following approved procedures under direction of the Lead COR/COR/PI. (**major**)
   a. Helicopter
   b. Bait trapping
2. WH&Bs must not be captured by snares or net gunning. (**major**)
3. Chemical immobilization must only be used for capture under exceptional circumstances and under the direct supervision of an on-site veterinarian experienced with the technique. (**major**)

B. Helicopter Drive Trapping

1. The helicopter must be operated using pressure and release methods to herd the animals in a desired direction and should not repeatedly evoke erratic behavior in the WH&Bs causing injury or exhaustion. Animals must not be pursued to a point of exhaustion; the on-site veterinarian must examine WH&Bs for signs of exhaustion. (**major**)
2. The rate of movement and distance the animals travel must not exceed limitations set by the Lead COR/COR/PI who will consider terrain, physical barriers, access limitations, weather, condition of the animals, urgency of the operation (animals facing drought, starvation, fire, etc.) and other factors. (**major**)
   a. WH&Bs that are weak or debilitated must be identified by BLM staff or the contractors. Appropriate gather and handling methods should be used according to the direction of the Lead COR/COR/PI. (**major**)
   b. The appropriate herding distance and rate of movement must be determined on a case-by-case basis considering the weakest or smallest animal in the group (e.g., foals, pregnant mares, or horses that are weakened by body condition, age, or poor health) and the range and environmental conditions present. (**major**)
   c. Rate of movement and distance travelled must not result in exhaustion at the trap site, with the exception of animals requiring capture that have an existing severely compromised condition prior to gather. Where compromised animals cannot be left on the range or where doing so would only serve to prolong their suffering, euthanasia will be performed in accordance with BLM policy. (**major**)
3. WH&Bs must not be pursued repeatedly by the helicopter such that the rate of movement and distance travelled exceeds the limitation set by the Lead

COR/COR/PI. Abandoning the pursuit or alternative capture methods may be considered by the Lead COR/COR/PI in these cases. (**major**)

4. When WH&Bs are herded through a fence line en route to the trap, the Lead COR/COR/PI must be notified by the contractor. The Lead COR/COR/PI must determine the appropriate width of the opening that the fence is let down to allow for safe passage through the opening. The Lead COR/COR/PI must decide if existing fence lines require marking to increase visibility to WH&Bs. (**major**)
5. The helicopter must not come into physical contact with any WH&B. The physical contact of any WH&B by helicopter must be documented by Lead COR/COR/PI along with the circumstances. (**major**)
6. WH&Bs may escape or evade the gather site while being moved by the helicopter. If there are mare/dependent foal pairs in a group being brought to a trap and half of an identified pair is thought to have evaded capture, multiple attempts by helicopter may be used to bring the missing half of the pair to the trap or to facilitate capture by roping. In these instances, animal condition and fatigue must be evaluated by the Lead COR/COR/PI or on-site veterinarian on a case-by-case basis to determine the number of attempts that can be made to capture an animal.(**major**)
7. Horse captures must not be conducted when ambient temperature at the trap site is below 10ºF or above 95ºF without approval of the Lead COR/COR/PI. Burro captures must not be conducted when ambient temperature is below 10ºF or above 100ºF without approval of the Lead COR/COR/PI. The Lead COR/COR/PI will not approve captures when the ambient temperature exceeds 105 ºF. (**major**)

C. Roping

1. The roping of any WH&B must be approved prior to the procedure by the Lead COR/COR/PI. (**major**).
2. The roping of any WH&B must be documented by the Lead COR/COR/PI along with the circumstances. WH&Bs may be roped under circumstances which include but are not limited to the following: reunite a mare or jenny and her dependent foal; capture nuisance, injured or sick WH&Bs or those that require euthanasia; environmental reasons such as deep snow or traps that cannot be set up due to location or environmentally sensitive designation; and public and animal safety or legal mandates for removal. (**major**)
3. Ropers should dally the rope to their saddle horn such that animals can be brought to a stop as slowly as possible and must not tie the rope hard and fast to the saddle so as to intentionally jerk animals off their feet. (**major**)
4. WH&Bs that are roped and tied down in recumbency must be continuously observed and monitored by an attendant at a maximum of 100 feet from the animal. (**major**)
5. WH&Bs that are roped and tied down in recumbency must be untied within 30 minutes. (**major**)
6. If the animal is tied down within the wings of the trap, helicopter drive trapping within the wings will cease until the tied-down animal is removed. (**major**)
7. Sleds, slide boards, or slip sheets must be placed underneath the animal's body to move and/or load recumbent WH&Bs. (**major**)
8. Halters and ropes tied to a WH&B may be used to roll, turn, position or load a recumbent animal, but a WH&B must not be dragged across the ground by a halter or rope attached to its body while in a recumbent position. (**major**)

9. Animals captured by roping must be evaluated by the on-site/on-call veterinarian within four hours after capture, marked for identification at the trap site, and be re-evaluated periodically as deemed necessary by the on-site/on-call veterinarian. (**major**)

D. Bait Trapping
1. WH&Bs may be lured into a temporary trap using bait (feed, mineral supplement, water) or sexual attractants (mares/jennies in heat) with the following requirements:
   a. The period of time water sources other than in the trap site are inaccessible must not adversely affect the wellbeing of WH&Bs, wildlife or livestock, as determined by the Lead COR/COR/PI. (**major**)
   b. Unattended traps must not be left unobserved for more than 12 hours. (**major**)
   c. Mares/jennies and their dependent foals must not be separated unless for safe transport. (**major**)
   d. WH&Bs held for more than 12 hours must be provided with accessible clean water at a minimum rate of ten gallons per 1000 pound animal per day, adjusted accordingly for larger or smaller horses, burros and foals and environmental conditions. (**major**)
   e. WH&Bs held for more than 12 hours must be provided good quality hay at a minimum rate of 20 pounds per 1000 pound adult animal per day, adjusted accordingly for larger or smaller horses, burros and foals. (**major**)
      1) Hay must not contain poisonous weeds, debris, or toxic substances. (**major**)
      2) Hay placement must allow all WH&Bs to eat simultaneously. (**major**)

II. WILD HORSE AND BURRO CARE

A. Veterinarian
1. On-site veterinary support must be provided for all helicopter gathers and on-site or on-call support must be provided for bait trapping. (**major**)
2. Veterinary support must be under the direction of the Lead COR/COR/PI. The on-site/on-call veterinarian will provide consultation on matters related to WH&B health, handling, welfare, and euthanasia at the request of the Lead COR/COR/PI. All decisions regarding medical treatment or euthanasia will be made by the on-site Lead COR/COR/PI. (**major**)

B. Care
1. Feeding and Watering
   a. Adult WH&Bs held in traps or temporary holding pens for longer than 12 hours must be fed every morning and evening with water available at all times other than when animals are being sorted or worked. (**major)**
   b. Water must be provided at a minimum rate of ten gallons per 1000 pound animal per day, adjusted accordingly for larger or smaller horses, burros and foals, and environmental conditions, with each trough placed in a separate location of the pen (i.e. troughs at opposite ends of the pen). . (**major**)
   c. Good quality hay must be fed at a minimum rate of 20 pounds per 1000 pound adult animal per day, adjusted accordingly for larger or smaller horses, burros and foals. (**major**)
      i. Hay must not contain poisonous weeds or toxic substances. (**major**)
      ii. Hay placement must allow all WH&Bs to eat simultaneously. (**major**)
   d. When water or feed deprivation conditions exist on the range prior to the gather,

the Lead COR/COR/PI should adjust the watering and feeding arrangements in consultation with the onsite veterinarian as necessary to provide for the needs of the animals. (minor)

2. Dust abatement
   a. Dust abatement by spraying the ground with water must be employed when necessary at the trap site and temporary holding facility. (**major**)

Trap Site

   a. Dependent foals or weak/debilitated animals must be separated from other WH&Bs at the trap site to avoid injuries during transportation to the temporary holding facility. Separation of dependent foals from mares must not exceed four hours unless the Lead COR/COR/PI authorizes a longer time or a decision is made to wean the foals. (**major**)

3. Temporary Holding Facility
   a. All WH&Bs in confinement must be observed at least once daily to identify sick or injured WH&Bs and ensure adequate food and water. (**major**)
   b. Foals must be reunited with their mares/jennies at the temporary holding facility within four hours of capture unless the Lead COR/COR/PI authorizes a longer time or foals are old enough to be weaned during the gather. (**major**)
   c. Non-ambulatory WH&Bs must be located in a pen separate from the general population and must be examined by the BLM horse specialist and/or on-call or on-site veterinarian as soon as possible, no more than four hours after recumbency is observed. Unless otherwise directed by a veterinarian, hay and water must be accessible to an animal within six hours after recumbency.(**major**)
   d. Alternate pens must be made available for the following: (**major**)
      1) WH&Bs that are weak or debilitated
      2) Mares/jennies with dependent foals
   e. Aggressive WH&Bs causing serious injury to other animals should be identified and relocated into alternate pens when possible. (minor)
   f. WH&Bs in pens at the temporary holding facility should be maintained at a proper stocking density such that when at rest all WH&Bs occupy no more than half the pen area. (minor)

C. Biosecurity

1. Health records for all saddle and pilot horses used on WH&B gathers must be provided to the Lead COR/COR/PI prior to joining a gather, including: (**major**)
   a. Certificate of Veterinary Inspection (Health Certificate, within 30 days).
   b. Proof of:
      1) A negative test for equine infectious anemia (Coggins or EIA ELISA test) within 12 months.
      2) Vaccination for tetanus, eastern and western equine encephalomyelitis, West Nile virus, equine herpes virus, influenza, *Streptococcus equi*, and rabies within 12 months.
2. Saddle horses, pilot horses and mares used for bait trapping lures must not be removed from the gather operation (such as for an equestrian event) and allowed to return unless they have been observed to be free from signs of infectious disease for a period of at least three weeks and a new Certificate of Veterinary Examination is obtained after three weeks and prior to returning to the gather. (**major**)

3. WH&Bs, saddle horses, and pilot horses showing signs of infectious disease must be examined by the on-site/on-call veterinarian. (**major**)
    a. Any saddle or pilot horses showing signs of infectious disease (fever, nasal discharge, or illness) must be removed from service and isolated from other animals on the gather until such time as the horse is free from signs of infectious disease and approved by the on-site/on-call veterinarian to return to the gather. (**major**)
    b. Groups of WH&Bs showing signs of infectious disease should not be mixed with groups of healthy WH&Bs at the temporary holding facility, or during transport. (minor)
4. Horses not involved with gather operations should remain at least 300 yards from WH&Bs, saddle horses, and pilot horses being actively used on a gather. (minor)

III. HANDLING

A. Willful Acts of Abuse
1. Hitting, kicking, striking, or beating any WH&B in an abusive manner is prohibited. (**major**)
2. Dragging a recumbent WH&B without a sled, slide board or slip sheet is prohibited. Ropes used for moving the recumbent animal must be attached to the sled, slide board or slip sheet unless being loaded as specified in Section II. C. 8. (**major**)
3. There should be no deliberate driving of WH&Bs into other animals, closed gates, panels, or other equipment. (minor)
4. There should be no deliberate slamming of gates and doors on WH&Bs. (minor)
5. There should be no excessive noise (e.g., constant yelling) or sudden activity causing WH&Bs to become unnecessarily flighty, disturbed or agitated. (minor)

B. General Handling
1. All sorting, loading or unloading of WH&Bs during gathers must be performed during daylight hours except when unforeseen circumstances develop and the Lead COR/CO/PI approves the use of supplemental light. (**major**)
2. WH&Bs should be handled to enter runways or chutes in a forward direction. (minor)
3. WH&Bs should not remain in single-file alleyways, runways, or chutes longer than 30 minutes. (minor)
4. Equipment except for helicopters should be operated and located in a manner to minimize flighty behavior . (minor)

C. Handling Aids
1. Handling aids such as flags and shaker paddles must be the primary tools for driving and moving WH&Bs during handling and transport procedures. Contact of the flag or paddle end of primary handling aids with a WH&B is allowed. Ropes looped around the hindquarters may be used from horseback or on foot to assist in moving an animal forward or during loading. (**major**)
2. Electric prods must not be used routinely as a driving aid or handling tool. Electric prods may be used in limited circumstances only if the following guidelines are followed:
    a. Electric prods must only be a commercially available make and model that uses DC battery power and batteries should be fully charged at all times. (**major**)
    b. The electric prod device must never be disguised or concealed. (**major**)
    c. Electric prods must only be used after three attempts using other handling aids

(flag, shaker paddle, voice or body position) have been tried unsuccessfully to move the WH&Bs. (**major**)

d. Electric prods must only be picked up when intended to deliver a stimulus; these devices must not be constantly carried by the handlers. (**major**)
e. Space in front of an animal must be available to move the WH&B forward prior to application of the electric prod. (**major**)
f. Electric prods must never be applied to the face, genitals, anus, or underside of the tail of a WH&B. (**major**)
g. Electric prods must not be applied to any one WH&B more than three times during a procedure (e.g., sorting, loading) except in extreme cases with approval of the Lead COR/COR/PI. Each exception must be approved at the time by the Lead COR/COR/PI. (**majo**r)
h. Any electric prod use that may be necessary must be documented daily by the Lead COR/COR/PI including time of day, circumstances, handler, location (trap site or temporary holding facility), and any injuries (to WH&B or human). (**major**)

IV. TRANSPORTATION

A. General

1. All sorting, loading, or unloading of WH&Bs during gathers must be performed during daylight hours except when unforeseen circumstances develop and the Lead COR/CO/PI approves the use of supplemental light. (**major**)
2. WH&Bs identified for removal should be shipped from the temporary holding facility to a BLM facility within 48 hours. (minor)
   a. Shipping delays for animals that are being held for release to range or potential on-site adoption must be approved by the Lead COR/COR/PI. (**major**)
3. Shipping should occur in the following order of priority; 1) debilitated animals, 2) pairs, 3) weanlings, 4) dry mares and 5) studs. (minor)
4. Planned
5. transport time to the BLM preparation facility from the trap site or temporary holding facility must not exceed 10 hours. (**major**)
6. WH&Bs should not wait in stock trailers and/or semi-trailers at a standstill for more than a combined period of three hours during the entire journey. (minor)

B. Vehicles

1. Straight-deck trailers and stock trailers must be used for transporting WH&Bs. (**major**)
   a. Two-tiered or double deck trailers are prohibited. (**major**)
   b. Transport vehicles for WH&Bs must have a covered roof or overhead bars containing them such that WH&Bs cannot escape. (**major**)
2. WH&Bs must have adequate headroom during loading and unloading and must be able to maintain a normal posture with all four feet on the floor during transport without contacting the roof or overhead bars. (**major**)
3. The width and height of all gates and doors must allow WH&Bs to move through freely. (**major**)
4. All gates and doors must open and close easily and be able to be secured in a closed position. (**major**)
5. The rear door(s) of the trailers must be capable of opening the full width of the trailer.

(**major**)

6. Loading and unloading ramps must have a non-slip surface and be maintained in proper working condition to prevent slips and falls. (**major**)
7. Transport vehicles more than 18 feet and less than 40 feet in length must have a minimum of one partition gate providing two compartments; transport vehicles 40 feet or longer must have at least two partition gates to provide a minimum of three compartments. (**major**)
8. All partitions and panels inside of trailers must be free of sharp edges or holes that could cause injury to WH&Bs. (**major**)
9. The inner lining of all trailers must be strong enough to withstand failure by kicking that would lead to injuries. (**major**)
10. Partition gates in transport vehicles should be used to distribute the load into compartments during travel. (minor)
11. Surfaces and floors of trailers must be cleaned of dirt, manure and other organic matter prior to the beginning of a gather. (**major**)

C. Care of WH&Bs during Transport Procedures

1. WH&Bs that are loaded and transported from the temporary holding facility to the BLM preparation facility must be fit to endure travel. (**major**)
   a. WH&Bs that are non-ambulatory, blind in both eyes, or severely injured must not be loaded and shipped unless it is to receive immediate veterinary care or euthanasia. (**major**)
   b. WH&Bs that are weak or debilitated must not be transported without approval of the Lead COR/COR/PI in consultation with the on-site veterinarian. Appropriate actions for their care during transport must be taken according to direction of the Lead COR/COR/PI. (**major**)
2. WH&Bs should be sorted prior to transport to ensure compatibility and minimize aggressive behavior that may cause injury. (minor)
3. Trailers must be loaded using the minimum space allowance in all compartments as follows: (**major**)
   a. 12 square feet per adult horse.
   b. 6.0 square feet per dependent horse foal.
   c. 8.0 square feet per adult burro.
   d. 4.0 square feet per dependent burro foal.
4. The Lead COR/COR/PI in consultation with the receiving Facility Manager must document any WH&B that is recumbent or dead upon arrival at the destination. (**major**)
   a. Non-ambulatory or recumbent WH&Bs must be evaluated on the trailer and either euthanized or removed from the trailers using a sled, slide board or slip sheet. (**major**)
5. Saddle horses must not be transported in the same compartment with WH&Bs. (**major**)

V. EUTHANASIA or DEATH

A. Euthanasia Procedure during Gather Operations

1. An authorized, properly trained, and experienced person as well as a firearm appropriate for the circumstances must be available at all times during gather operations. When the travel time between the trap site and temporary holding facility

exceeds one hour or if radio or cellular communication is not reliable, provisions for euthanasia must be in place at both the trap site and temporary holding facility during the gather operation. (**major**)

2. Euthanasia must be performed according to American Veterinary Medical Association euthanasia guidelines (2013) using methods of gunshot or injection of an approved euthanasia agent. (**major**)
3. The decision to euthanize and method of euthanasia must be directed by the Authorized Officer or their Authorized Representative(s) that include but are not limited to the Lead COR/COR/PI who must be on site and may consult with the on-site/on-call veterinarian. (**major**)
4. Photos needed to document an animal's condition should be taken prior to the animal being euthanized. No photos of animals that have been euthanized should be taken. An exception is when a veterinarian or the Lead COR/COR/PI may want to document certain findings discovered during a postmortem examination or necropsy. (minor)
5. Any WH&B that dies or is euthanized must be documented by the Lead COR/COR/PI including time of day, circumstances, euthanasia method, location, a description of the age, gender, and color of the animal and the reason the animal was euthanized. (**major**)
6. The on-site/on-call veterinarian should review the history and conduct a postmortem physical examination of any WH&B that dies or is euthanized during the gather operation. A necropsy should be performed whenever feasible if the cause of death is unknown. (minor)

B. Carcass Disposal

1. The Lead COR/COR/PI must ensure that appropriate equipment is available for the timely disposal of carcasses when necessary on the range, at the trap site, and temporary holding facility. (**major**)
2. Disposal of carcasses must be in accordance with state and local laws. (**major**)
3. WH&Bs euthanized with a barbiturate euthanasia agent must be buried or otherwise disposed of properly. (**major**)
4. Carcasses left on the range should not be placed in washes or riparian areas where future runoff may carry debris into ponds or waterways. Trenches or holes for buried animals should be dug so the bottom of the hole is at least 6 feet above the water table and 4-6 feet of level earth covers the top of the carcass with additional dirt mounded on top where possible. (minor)

CAWP
Required Documentation and Responsibilities of Lead COR/COR/PI
Required Documentation

Section	Documentation
II.B.5	Helicopter contact with any WH&B.
II.C.2	Roping of any WH&B.
III.B.3.a and III.B.4.b	Reason for allowing longer than four hours to reunite foals with mares/jennies. Does not apply if foals are being weaned.
III.C.1	Health status of all saddle and pilot horses.
IV.C.2.h	All uses of electric prod.
V.C.4	Any WH&B that is recumbent or dead upon arrival at destination following transport.
VI.A.5	Any WH&B that dies or is euthanized during gather operation.

Responsibilities

Section	Responsibility
I.A.10	Approve materials used in construction of finger gates in bait trapping
II.A.1	Direct gather procedures using approved gather technique.
II.B. 2	Determine rate of movement and distance limitations for WH&B helicopter gather.
II.B.2.a	Direct appropriate gather/handling methods for weak or debilitated WH&B.
II.B.3	Determine whether to abandon pursuit or use other capture method in order to avoid repeated pursuit of WH&B.
II.B.4	Determine width and need for visibility marking when using opening in fence en route to trap.
II.B.6	Determine number of attempts that can be made to capture the missing half of a mare/foal pair that has become separated.
II.B.7	Determine whether to proceed with gather when ambient temperature is outside the range of 10°F to 95°F for horses or 10°F to 100°F for burros.
II.C.1	Approve roping of any WH&B.
II.D.1.a	Determine period of time that water outside a bait trap is inaccessible such that wellbeing of WH&Bs, wildlife, or livestock is not adversely affected.
III.A.2	Direct and consult with on-site/on-call veterinarian on any matters related to WH&B health, handling, welfare and euthanasia.
III.B.1.e	Adjust feed/water as necessary, in consultation with onsite/on call veterinarian, to provide for needs of animals when water or feed deprivation conditions exist on range.
III.B.4.c	Determine provision of water and hay to non-ambulatory animals.
IV.C.2.g	Approve use of electric prod more than three times, for exceptional cases only.
V.A.1	Approve sorting, loading, or unloading at night with use of supplemental light.
V.A.2.a	Approve shipping delays of greater than 48 hours from temporary holding facility to BLM facility.
V.C.1.b	Approve of transport and care during transport for weak or debilitated WH&B.
VI.A.3	Direct decision regarding euthanasia and method of euthanasia for any WH&B; may consult with on-site/on-call veterinarian.
VI.B.1	Ensure that appropriate equipment is available for carcass disposal.

APPENDIX C
Standard Operating Procedures for Field Castration (Gelding) of Wild Horse Stallions

June 2011

Gelding will be performed with general anesthesia and by a veterinarian. The combination of pharmaceutical compounds used for anesthesia, method of physical restraint, and the specific surgical technique used will be at the discretion of the attending veterinarian with the approval of the authorized officer (I.M. 2009-063).

Pre-surgery Animal Selection, Handling and Care

1. Stallions selected for gelding will be greater than 6 months of age and less than 20 years of age.
2. All stallions selected for gelding will have a Henneke body condition score of 3 or greater. No animals which appear distressed, injured or in failing health or condition will be selected for gelding.
3. Stallions will not be gelded within 36 hours of capture and no animals that were roped during capture will be gelded at the temporary holding corrals for rerelease.
4. Whenever possible, a separate holding corral system will be constructed on site to accommodate the stallions that will be gelded. These gelding pens will include a minimum of 3 pens to serve as a working pen, recovery pen(s), and holding pen(s). An alley and squeeze chute built to the same specifications as the alley and squeeze chutes used in temporary holding corrals (solid sides in alley, minimum 30 feet in length, squeeze chute with non-slip floor) will be connected to the gelding pens.
5. When possible, stallions selected for gelding will be separated from the general population in the temporary holding corral into the gelding pens, prior to castration.
6. When it is not possible or practical to build a separate set of pens for gelding, the gelding operation will only proceed when adequate space is available to allow segregation of gelded animals from the general population of stallions following surgery. At no time will recently anesthetized animals be returned to the general population in a holding corral before they are fully recovered from anesthesia.
7. All animals in holding pens will have free access to water at all times. Water troughs will be removed from working and recovery pens prior to use.
8. Prior to surgery, animals in holding pens may be held off feed for a period of time (typically 12-24 hours) at the recommendation and direction of the attending veterinarian.
9. The final determination of which specific animals will be gelded will be based on the professional opinion of the attending veterinarian in consultation with the Authorized Officer.
10. Whether the procedure will proceed on a given day will be based on the discretion of the attending veterinarian in consultation with the Authorized Officer taking into consideration the prevailing weather, temperature, ground conditions and pen set up. If these field situations can't be remedied, the procedure will be delayed until they can be, the stallions will be transferred to a prep facility, gelded, and later returned, or they will be released to back to the range as intact stallions.

Gelding Procedure

1. All gelding operations will be performed under a general anesthetic administered by a qualified and experienced veterinarian. Stallions will be restrained in a portable squeeze chute to

allow the veterinarian to administer the anesthesia.
2. The anesthetics used will be based on a xylazine/ketamine combination protocol. Drug dosages and combinations of additional drugs will be at the discretion of the attending veterinarian.
3. Animals may be held in the squeeze chute until the anesthetic takes effect or may be released into the working pen to allow the anesthesia to take effect. If recumbency and adequate anesthesia is not achieved following the initial dose of anesthetics, the animal will either be redosed or the surgery will not be performed on that animal at the discretion of the attending veterinarian.
4. Once recumbent, rope restraints or hobbles will be applied for the safety of the animal, the handlers and the veterinarian.
5. The specific surgical technique used will be at the discretion of the attending veterinarian.
6. Flunixin meglamine or an alternative analgesic medication will be administered prior to recovery from anesthesia at the professional discretion of the attending veterinarian.
7. Tetanus prophylaxis will be administered at the time of surgery.
8. Other medications may also be administered at the time of surgery at the professional discretion of the attending veterinarian.
9. All geldings will be allowed to recover from anesthesia within the working pen or the adjacent recovery pen. Once, fully recovered each gelding will be transferred to the gelding holding pen(s). Animals will remain segregated from intact stallions for at least 24 hours following surgery or until their release.
10. Any stallions determined or believed to be a cryptorchid will be allowed to recover from the anesthesia, marked for later recognition, and shipped to a BLM prep facility for appropriate surgery or euthanasia if it is determined that they cannot be fully castrated. At no time will a partial castration be performed. Because cryptorchidism is an inherited condition, cryptorchid stallions should never be released back into an HMA.
11. Gelded animals will be freeze marked on their left hip with an identifying mark to minimize the potential for future recapture and to facilitate post-treatment monitoring. Each State will establish its own marking system in compliance with their State Brand Board. For example, Nevada BLM will utilize the identifying freeze mark on the hip (to be determined) as well as a 2 inch “F” freeze mark on the left side of the neck per agreement with the NV Brand Board.

Post-operative handling, care and monitoring
1. All animals that have fully recovered from anesthesia will have free access to water and hay prior to subsequent release.
2. All geldings will be held at least overnight for observation. Animals will not be left unattended for at least 3 hours following the procedure.
3. The attending veterinarian will observe all animals 12-24 hours after the procedure or again prior to release. Geldings will be released no later than 48 hours following surgery near a water source in their home range when possible.
4. Any gelding observed have complications will be held at the gather site until his condition improves or be shipped to a holding facility until he is able to be returned to the range.
5. Gelded animals would be monitored periodically for complications for approximately 7-10 days post-surgery. This monitoring will be completed either through aerial recon if available or field observations from major roads and trails. It is not anticipated that all the geldings will be observed but the goal is to detect complications if they are occurring and determine if the horses are freely moving about the HMA.
6. Animals found on the range with serious gelding complications will either be recaptured for treatment, if possible or euthanized as an act of mercy if necessary.

7. Observations of the long term outcomes of gelding will be recorded during routine resource monitoring work. Such observations will include but may not limited to band size, social interactions with other geldings and harem bands, distribution within their habitat, forage utilization and activities around key water sources.

APPENDIX D
Win Equus Population Modeling Results

Population Model

Conger and Frisco 2015 Population Modeling

To complete the population modeling for the Conger and Frisco Herd Management Areas, version 1.40 of the WinEquus program, created April 2, 2002, was utilized.

Objectives of Population Modeling

Review of the data output for each of the simulations provided many use full comparisons of the possible outcomes for each alternative. Some of the questions that need to be answered through the modeling include:

• Do any of the Alternatives "crash" the population?

• What effect does fertility control have on population growth rate?

• What effects do the different alternatives have on the average population size?

• What effects do the different alternatives have on the genetic health of the herd?

Population Data, Criteria, and Parameters utilized for Population Modeling

All simulations used the survival probabilities, foaling rates, and sex ratio at birth that was supplied with the Winn Equus population for the Garfield HMA.

Sex ratio at Birth:

Frisco	Conger
41% Females	50% Females
59% Males	50% Males

A 94% effectiveness of PZP for 1 year in population growth suppression was used when fertility control was utilized in the modeling,

The following table displays the contraception parameters utilized in the population model for Alternative 2-4:

Contraception Criteria

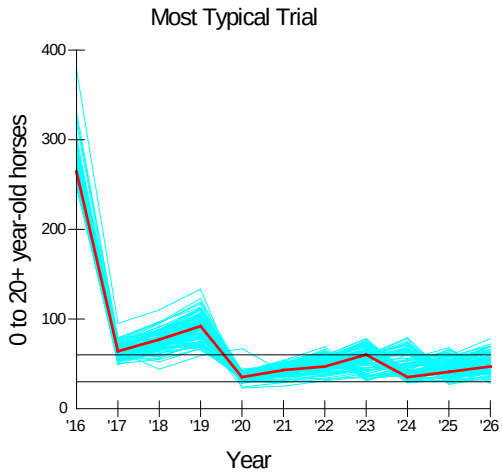
Age	Percentages for Fertility Treatment
1	0%
2	100%
3	100%
4	100%
5	100%
6	100%

7	100%
8	100%
9	100%
10-14	100%
15-19	100%
20+	100%

Population Modeling Parameters Modeling Parameter	**Gather and Removals Only**		**Population Growth Suppression using PZP**		**Gather and Removal with Population Growth Suppression using PZP**		**No Gather and Removals or Population Growth Suppression using PZP**
Management by removal only	Yes		No		No		No
Threshold Population Size Following Gathers	Conger	Frisco	Conger	Frisco	Conger	Frisco	N/A
	80	60	80	60	80	60	
Target Population Size Following gather	40	30	40	30	40	30	N/A
Gather for Population Growth Suppression regardless of population size	No		Yes		Yes		N/A
Gather continue after removals to treat additional females	N/A		Yes		Yes		N/A

Population Modeling Criteria

The following summarizes the population modeling criteria that are common to the Proposed Action and all alternatives:



- Starting year: 2016
- Initial Gather Year: 2016
- Gather interval: regular interval of three years
- Gather for fertility treatment regardless of population size: No
- Continue to gather after reduction to treat females: Yes
- Sex ratio at birth: 59% males
- Percent of the population that can be gathered: 80%
- Minimum age for long term holding facility horses: Not Applicable
- Foals are included in the AML
- Simulations were run for 10 years with 100 trials each

APPENDIX E
Interdisciplinary Team Checklists

Project Title: Population Control Research Wild Horse Gather for the Conger and Frisco Herd Management Areas
NEPA Log Number: DOI-BLM-UT-W020-2015-0017-EA
File/Serial Number:
Project Leader: Eric Reid/Chad Hunter

DETERMINATION OF STAFF: (Choose one of the following abbreviated options for the left column)
NP = not present in the area impacted by the proposed or alternative actions
NI = present, but not affected to a degree that detailed analysis is required
PI = present with potential for relevant impact that need to be analyzed in detail in the EA

Determi-nation	Resource	Rationale for Determination	Signature	Date
RESOURCES AND ISSUES CONSIDERED (INCLUDES SUPPLEMENTAL AUTHORITIES APPENDIX 1 H-1790-1)				
NI	Air Quality	There are would be no impact to air quality as a result of the proposed action.	/s/ Paul Caso	10/9/15
NI	Areas of Critical Environmental Concern	There are two ACEC's (Wah Wah Mountains and Crystal Peak) that are located in the proposed project areas. They are both designated as closed to ORV use. The project, as proposed, would not impact these ACEC's.	/s/ Teresa Frampton	9/25/15
NP	Cultural Resources	No historic properties affected	/s/ Stacey Whitman Moore	9/28/15
NI	Greenhouse Gas Emissions	BLM does not have the ability to associate an action's contribution in a localized area to impact global climate change. Further, an IPCC assessment states that, "difficulties remain in attributing observed temperature changes at a smaller than continental scale"	/s/ Cindy Ledbetter	9/11/15
NI	Environmental Justice	Low income or minority populations would not be disproportionately impacted by the project.	/s/ Cindy Ledbetter	9/11/15
NI	Farmlands (Prime or Unique)	The only possible soil disturbance related to the proposed action would occur on shallow soils that are not suitable for farmlands.	/s/ Bill Thompson	11/19/15
NI	Floodplains	Floodplains would not be impacted by the proposed action.	/s/ Paul Caso	10/9/15
NP	Fire/Fuels Management	The project, as proposed sill not impact fire or fuels management.	/s/ Gary Bishop	9/25/15
NI	Geology / Mineral Resources/Energy Production	Geology / Mineral Resources are present but will not be impacted by Proposed Action.	/s/ Todd Leeds, P.G.	9/25/15
NI	Invasive Species/Noxious Weeds (EO 13112)	Noxious and/or invasive species would not be impacted by the proposed project.	/s/R.B. Probert	11/30/15
NI	Lands/Access	The project, as proposed, would not affect access to public lands.	/s/ Teresa Frampton	9/25/15
PI	Livestock Grazing	Removal of excess horses would benefit the livestock grazing program through reduced competition for vegetation and water resources.	/s/ Brian Taylor	10/5/15

Determi-nation	Resource	Rationale for Determination	Signature	Date
NI	Migratory Birds	Given the low magnitude and short duration of the proposed action, no impacts to migratory birds are anticipated. Migratory birds may benefit from the reduction of herd numbers.	/s/ James Priest	9/25/15
NP	National Historic Trails	No potential to affect NHT	/s/ Stacey Whitman Moore	9/28/15
NI	Native American Religious Concerns	Tribal consultation was initiated on October 1, 2015. Tribes did not express any concerns regarding the proposed project.	/s/ Stacey Whitman Moore	11/4/15
NP	Paleontology	There are no known paleontological resources within the project area.	/s/ Cindy Ledbetter	9/11/15
NI	Property Boundary Evaluation	The property markers will not be affected by the project.	/s/ Kyle Monroe	9/25/15
PI	Rangeland Health Standards	The potential for maintenance of Rangeland Health would be increased by removing wild horses to keep their numbers on the HMA within the appropriate management level. If no action is taken, rangeland health will deteriorate in areas where wild horses spend most of their time.	/s/ Brian Taylor	10/5/15
NI	Recreation	There are no developed recreational sites that would be affected by the proposed activity and casual recreation use would not be affected.	/s/ Teresa Frampton	9/25/15
NI	Sensitive Animal Species	Sensitive wildlife species that could be found within or near the proposed action include but limited to: golden eagle, bald eagle, burrowing owl, Ferruginous hawk, kit fox, Brewer's sparrow, loggerhead shrike, sage sparrow and various bat species. Given the low magnitude and duration of the proposed action, no substantial impacts to these species are anticipated to occur and therefore do no further analysis is required.	/s/James Priest	9/28/15
NI	Socio-Economics	No quantifiable increased or decreased economic impact to the local area would be caused by the proposed action.	/s/ Cindy Ledbetter	9/11/15
NI	Soils	Soils would not be impacted by the proposed action.	/s/ Paul Caso	10/9/15
NI	Threatened, Endangered, Candidate or Special Status Plant Species	There are no known federally-listed plants within the Conger HMA. There is one known BLM Sensitive Plant Species, sand-loving buckwheat (*Eriogonum nummulare* var. *ammophilum*) that is found on the northwest and southern fringes of the Conger HMA. The project proposal is to merely conduct a wild horse study to better understand and manage wild horse populations. This study is not anticipated to have negative impacts on this sensitive plant species.	/s/DWhitaker	10/20/15
NP	Threatened, Endangered, or Candidate Animal Species	There are no known federally listed fish or wildlife species known to occur within or near the proposed action.	/s/ James Priest	9/28/15
NP	Wastes (hazardous or solid)	There are no hazardous waste sites within the project area. The project will not generate hazardous waste.	/s/ Todd Leeds, P.G.	9/28/15
NI	Water Resources/Quality (drinking/surface/ground)	There are would be no impact to water resources/quality as a result of the proposed action.	/s/ Paul Caso	10/9/15

Determi-nation	Resource	Rationale for Determination	Signature	Date
NI	Water Rights	Water Rights would not be impacted by the proposed action.	/s/ Paul Caso	10/9/15
NI	Wetlands/Riparian Zones	Gathering wild horses would occur far from any riparian areas in the HMA. There would be no disturbance to riparian areas in the HMA.	/s/ Bill Thompson	11/19/15
NI	Wilderness/WSA	There are two WSA's (Conger Mountain and King Top) that are located within the proposed project area, but the project, as proposed, would not impact the WSA's.	/s/ Teresa Frampton	9/25/15
NI	Wildlife and Fish Excluding Designated/Special Status Species	General wildlife species, such as mule deer, antelope, mountain lion, coyote, rattle snakes, lizards and jack rabbits occur within the scope of the proposed action. Managing herd numbers will benefit wildlife overall by reducing competition and improving range condition.	/s/ James Priest	9/28/15
NI	Woodland / Forestry	There are would be no impact to woodland or forestry products with the implementation of the proposed action.	/s/Eric Reid	8/27/15
PI	Vegetation Excluding Designated/Special Status Species	There are no anticipated negative impacts to range vegetation from the proposed horse gather. Very little ground disturbance is proposed. The removal of the excess Wild Horses will have a positive impact on the vegetative resource by decreasing the amount of use occurring on forage plants.	/s/ Brian Taylor	12/15/15
NI	Visual Resources	The proposed project is located within a small portion of the VRM Class III Classification and the remaining portions are in the Class IV classification. The proposed project would not impact visual resources.	/s/ Teresa Frampton	9/25/15
PI	Wild Horses and Burros	Wild Horse population within the Conger HMA would be brought to be within the established appropriate management levels set for the HMA by the removal of the excess wild horses. The research proposal could provide valuable information for future management of wild horse populations throughout the BLM. Any negative effects from the research proposal could be remedied over time to return the population to a more normal balance of reproductive males though removals of the geldings and releasing stallions from similar HMAs with in the field office if necessary. Habitat would improve directly from the removal of the excess animals and reducing the amount of use on the range within the HMA.	/s/Eric Reid	8/27/15
NI	Lands with Wilderness Characteristics	The project, as proposed, would not affect Lands with Wilderness Character.	/s/ Teresa Frampton	10/22/15

INTERDISCIPLINARY TEAM NEPA CHECKLIST

Project Title: Conger and Frisco Wild Horse Gelding and Demography Research

NEPA Log Number: DOI-BLM-UT-W020-2015-0017-EA
File/Serial Number:

Project Leader: Eric Reid/Chad Hunter

DETERMINATION OF STAFF: ***(Choose one of the following abbreviated options for the left column)***

NP = not present in the area impacted by the proposed or alternative actions
NI = present, but not affected to a degree that detailed analysis is required
PI = present with potential for relevant impact that need to be analyzed in detail in the EA
NC = (DNAs only) actions and impacts not changed from those disclosed in the existing NEPA documents cited in Section D of the DNA form.
The rationale column should include NI and NP discussions.

RESOURCES AND ISSUES CONSIDERED:

Determi-nation	Resource	Rationale for Determination	Signature	Date
NI	Air Quality	Air quality in the area is good as is typical of relatively undeveloped areas of the western U.S. The area meets NAAQS. Nothing in the proposal would affect current conditions.	A. Stephens	12/7/15
NP	Areas of Critical Environmental Concern	None within Field Office boundaries.	C. Hunter	11/23/15
NI	Cultural Resources	This gather will have no effect to significant cultural resources. The corral locations will be located on an area of existing disturbance. The possibility of finding intact cultural resources in these areas is minimal to non-existent. If an existing disturbed area cannot be located for the corral area, a cultural resource inventory will take place prior to the gather. If cultural resources are located during this inventory, the corral area will be moved to another location, which does not contain cultural resources.	Jamie Palmer	11/6/2015
NI	Greenhouse Gas Emissions	Releases of greenhouse gasses (GHG's), such as carbon monoxide, would occur as a result of operation of internal combustion engines being operated during the gather. The removal would occur in a very remote portion of Iron, Beaver and Millard counties and occur using improved county roads and lesser roads. Release of GHG's would be consistent with current levels of releases in the area and very short term.	A. Stephens	12/7/15
NI	Environmental Justice	No minority or economically disadvantaged groups would be affected.	C. Hunter	11/23/15
NP	Farmlands (Prime or Unique)	There is no soil survey completed for much of this area. There are likely soils in and adjacent to the herd unit capable of being prime or unique farmlands, however only when irrigation water is supplied. Where there is no irrigation water supplied, there are no prime or unique farmlands present.	C. Hunter	11/23/15
PI	Fish and Wildlife	Cedar City FO: The area is mapped as UDWR crucial summer mule deer, crucial yearlong pronghorn, and substantial yearlong rocky mountain elk habitat. Fawning for pronghorn April 15- June 15 and mule deer May 1 – June 15.	S. Whitfield	11/12/15

Determi-nation	Resource	Rationale for Determination	Signature	Date
		The area is also considered substantial yearlong chuckar habitat. However, the gather operations would occur outside the fawning seasons and the research activities wouldn't be greater than general public use of the area. Reducing horse numbers within the HMA would be beneficial and ensure the required forage availability for big game species throughout the year and during crucial big game fawning periods.		
NI	Floodplains	Nothing in the proposal would affect the functioning of a floodplain, nor would any of the alternatives effect the function of a floodplain. Therefore the action is consistent with Executive Order 11988.	C. Hunter	11/23/15
NI	Fuels/Fire Management	No impact to fire or fuels management	M. Mendenhall	11/5/15
NI	Geology / Mineral Resources/Energy Production	The transient and superficial nature of the activities proposed would not substantially impact any mineral resources that may be present in the project area.	E. Ginouves	11/4/15
PI	Hydrologic Conditions	Hydrologic conditions are variable throughout the Frisco HMA, but in general are thought to be relatively good. The only recent soil data that exists is unpublished data for parts of Beaver and Millard Counties. Fragile soils occur within the HMA. These are considered fragile primarily due to steep slopes. Field examination of some of the allotments during rangeland health evaluations revealed small areas with a moderate or higher departure from normal in soil stability. Excess numbers of horses are removing protective vegetative cover and are contributing to localized active gullying and overland flows. Soil compaction is a localized problem, especially where horses are trailing to and from water sources. See EA text under "Rangeland Health Standards" for more details.	A. Stephens	12/7/15
NI	Invasive Species/Noxious Weeds	As long as there is a stipulation (as in the SOPs) of the use of weed free hay during any bait trapping, and for any feeding purposes of wild horses and/or domestic horses at the gather site or at holding areas on public land.	C. Hunter	11/23/15
NI	Lands/Access	Any pending or authorized lands and realty actions in the project area would not be substantially affected by the proposed action as long as measures are taken to assure all rights by grant, permit or lease holders are upheld. Prior to any surface disturbing activities in the vicinity of potential lands projects, the lands and realty staff should be notified to assist in locating existing or pending lands actions that may be impacted.	M. Campeau	11/16/15
PI	Livestock Grazing	Livestock and wild horses compete directly for vegetative, water, and cover resources. Higher populations of wild horses mean more competition with livestock. Wild horse populations that are within AML reduce competition. When wild horse populations are above AML the livestock numbers must be reduced to not over utilize the vegetative and water resources.	C. Hunter	11/23/15
PI	Migratory Birds	Multiple migratory songbirds and raptors occur within the Frisco HMA including ferruginous hawks, red-tailed hawks and golden eagles.	S. Whitfield	11/12/15
NI	Native American Religious Concerns	Based on previous government to government consultations with the Paiute Indian Tribe of Utah, the Hopi Tribe and data	Jamie Palmer	11/6/2015

Determi-nation	Resource	Rationale for Determination	Signature	Date
		from recent ethnographic studies, this action would not adversely affect the physical integrity or limit access to any known sacred sites.		
NI	Paleontology	The transient and superficial nature of the activities proposed would not substantially impact any fossil resources that may be present in the project area.	E. Ginouves	11/4/15
PI	Rangeland Health Standards	This is addressed as part of the Rangeland Health Standards section of the EA.	C. Hunter	11/23/15
NI	Recreation	Recreation in the project area is dispersed, and some displacement may occur during gather operations, however impacts will not be substantial. Coordination is necessary with the Utah Division of Wildlife Resources to notify public of operations, and to avoid conflicts during hunting season.	D. Jacobson	12/7/15
NI	Socio-Economics	The proposed action will not in its self change the socio-economics of the area.	C. Hunter	11/23/15
PI	Soils	Under the current situation of currently permitted livestock numbers, wildlife numbers being what they are and wild horses above AML, inadequate residual vegetation (forage) and litter remain on areas of grazing allotments within the analysis area (as evidenced by Rangeland Health Information). Lack of protective ground cover directly affects the soil's exposure to the erosive elements of wind and water. A reduction in horse numbers would allow additional vegetation to remain on these key areas, thus providing additional protection to the soil surface. For the purposes of the EA, hydrologic conditions and soils are combined.	C. Hunter	11/23/15
NI	Special Status Plant Species	There are 3 candidate plant species (*Eriogonum spathulatum var. kayeae, Leipidium ostleri, Trifolium friscanum)* occur within the project area. The gather is not anticipated to have impacts on the candidate plant species. There are no BLM sensitive plant species have been identified to occur within the project area.	D. Fletcher	12/08/2015
PI	Special Status Animal Species	Pygmy rabbits, ferruginous hawk and big-eared bat have the potential to occur within the Frisco HMA. Reducing horse numbers within the HMA would ensure adequate forage and cover for wildlife species using the area. No threatened, endangered or candidate wildlife species are within the Frisco HMA.	S. Whitfield	11/12/15
NP	Wastes (hazardous or solid)	There are no known hazardous or solid wastes created from this activity.	Glenn Pepper	12/7/2015
PI	Water Resources/Quality (drinking/surface/ground)	The proposed action would not be expected to impact drinking/ground water quality. However, surface water quality associated with riparian areas may improve with reduced grazing/trampling impacts from wild horses.	A. Stephens	12/7/15
PI	Wetlands/Riparian Zones	Project stipulations minimize impacts to wetland/riparian areas. A reduction in wild horse numbers would be expected to be beneficial to most riparian areas associated with the proposed action where wild horses have impacted riparian functionality.	A. Stephens	12/07/15
NI	Wild and Scenic Rivers	There are no Wild and Scenic Rivers present within CCFO	A. Stephens	12/07/15

Determi-nation	Resource	Rationale for Determination	Signature	Date
NI	Wilderness/WSA	Placement of gather sites in previously disturbed areas, and along existing roads would ensure no impacts to areas which may have wilderness characteristics.	D. Jacobson	12/7/15
NI	Woodland / Forestry	No impact to Woodland/Forestry management	C. Peterson	11/5/15
PI	Vegetation	The proposed management and removal of excess wild horses would benefit vegetative resources by reducing utilization, trampling, and leaving more residual cover.	C. Hunter	12/7/15
NI	Visual Resources	The proposed action includes only minor temporary disturbance. The actions will not measurable impact visual resources.	D. Jacobson	12/7/15
PI	Wild Horses and Burros	Project is within the Frisco HMA and there would be direct impacts to wild horses. See EA	C. Hunter	11/23/15
NI	Lands with Wilderness Characteristics	The project would not change the character of the land scape in areas that have been identified as having lands with wilderness characteristics such as units UT-C010-199. The areas would still have wilderness characteristics after the proposed gather.	D. Jacobson	12/7/15

APPENDIX F

Observation Protocol and Ground Rules

These rules were created to ensure the safety of both the humans and the animals at the gather site(s).
A scheduled public observation day provides a more structured mechanism for interested members of the public to see the wild horse gather activities at a given site. The BLM attempts to allow the public to get an overall sense of the gather process and has available staff who can answer questions that the public may have. The public rendezvous at a designated place and are escorted by BLM representatives to and from the gather site.

- The Bureau of Land Management (BLM) will schedule observation days to provide the media and public opportunities to view activities during the wild horse gather.
- To provide a safe environment for the animals, BLM staff, contractors and members of the public/media, requests will be accepted on a first come, first served basis and be limited to 10 people per observation day unless otherwise approved by authorized BLM official over the gather. The BLM recommends all appointments be made as far in advance as possible in order to help us schedule and confirm your request, and will make every reasonable effort to accommodate the public.
- Observation days and gather operations may be suspended if bad weather conditions create unsafe flying conditions.
- The BLM will notify observers as soon as possible if an observation day is canceled due to bad weather.
- Observers must provide their own 4-wheel drive high clearance vehicle, appropriate shoes, clothing and food.
- Observers are prohibited from riding in government and contractor vehicles and equipment.
- Visitors arriving at the rendezvous site without an appointment will not be allowed to participate in the observation day.
- BLM representatives will escort visitors to and from the gather and/or temporary holding facility.
- Visitors will be assigned to a BLM representative and must stay with that person at all times.
- Visitors are NOT permitted to walk around the gather site unaccompanied by a BLM representative.
- The BLM will clearly identify observation areas and visitors must stay within these designated areas.
- Observers are prohibited from climbing/trespassing onto or in the trucks, equipment or corrals, which is the private property of the contractor.
- Visitors must direct their questions/comments to either a designated BLM representative or the BLM spokesperson on site, and not engage other BLM/contractor staff and disrupt their gather duties/responsibilities.
- BLM may make the BLM/contractor staff available during down times for a Q&A session.
- When given the signal that the helicopter is close to the gather site bringing horses in, visitors must sit down in areas specified by BLM representatives and must not move or talk as the horses are guided into the corral.
- Observers will be polite, professional and respectful to BLM managers and staff and the

contractor/employees.

- Visitors who do not cooperate and follow the rules will be escorted off the gather site by BLM law enforcement personnel, and will be prohibited in participating in any subsequent observation days.

- Non- Scheduled Observation day Protocol and Ground Rules
- Non-scheduled observation days are days when the public is welcome to attend a gather on public land, or on specified private lands where permission was granted. The public is responsible for their own safety and health in their travels to and from the gather site.
- BLM staff may be limited on these days to answer questions.
- Visitors must direct their questions/comments to either a designated BLM representative or the BLM spokesperson on site, and not engage other BLM/contractor staff and disrupt their gather duties/responsibilities.
- The public will be expected to remain in designated observation areas.
- Visitors are NOT permitted to walk around the gather site unaccompanied by a BLM representative.
- The BLM will clearly identify observation areas and visitors must stay within these designated areas.
- Observers are prohibited from climbing/trespassing onto or in the trucks, equipment or corrals, which is the private property of the contractor.
- Observers must provide their own 4-wheel drive high clearance vehicle, appropriate shoes, clothing and food.
- When given the signal that the helicopter is close to the gather site bringing horses in, visitors must sit down in areas specified by BLM representatives and must not move or talk as the horses are guided into the corral.
- Gather operations may be suspended if bad weather conditions create unsafe flying conditions. Notification of suspension of gather operations will be made to the public that is present as soon as possible.
- Visitors must direct their questions/comments to either a designated BLM representative or the BLM spokesperson on site, and not engage other BLM/contractor staff and disrupt their gather duties/responsibilities.
- BLM may make the BLM/contractor staff available during down times for a Q&A session.

Observers will be polite, professional and respectful to BLM managers and staff and the contractor/employees.

Visitors who do not cooperate and follow the rules will be escorted off the gather site by BLM law enforcement personnel, and will be prohibited in participating in any subsequent observation days.

APPENDIX G

Public Comments and Responses

A Preliminary Environmental Assessment (EA) for the Population Control Research Wild Horse Gather for the Conger and Frisco Herd Management Areas DOI-BLM-UT-W020-2015-0017-EA was available to the public for a 30-day review/comment period beginning on April 18, 2016 and ending May 17, 2016. Written comments were received from 7 individuals by mail from Beaver County and the general public. E-mail comments and form letters were received from approximately 6,000 individuals. Approximately 5,980 of these letters were in a form letter format, of which over 5,000 were in support of Alternative 2. Comments received after May 17, 2016 were not accepted. Many of these comments contained overlapping issues/concerns which were consolidated into 72 comments and 14 distinct topics. Many of the comments could be clarified or answered by referring to sections within the EA. Others were outside the scope of the document. All comments were considered, but only those which included substantive comments were addressed below. Changes were made from the Preliminary EA to this Final EA based upon those comments and public involvement. Comments which are clearly addressed in the EA are not contained below. Comments which state personal opinion or support/opposition to the gather but are not substantive or are outside of the scope of this document are included in the case file at the Fillmore Field Office. Below is a detailed summary of the substantive comments received and how BLM used these comments in preparing the final environmental assessment. In addressing the comments the references are to the Preliminary EA unless otherwise specified.

No.	Commenter	Comment	BLM Response
GATHER METHODS			
1.	Several	Several comments were received which stated concerns with helicopter gathering of wild horses. These comments are represented by the following.	Wild horses are moved during gather operations by herding and are not stampeded. The WFRHBA mandates the gather and removal of excess wild horses and specifically authorizes the use of helicopters in Section 9 of the Act. "In administering this Act, the Secretary may use or contract for the use of helicopters or, for the purpose of transporting captured animals, motor vehicles. Such use shall be undertaken only after a public hearing and under the direct supervision of the Secretary or of a duly authorized official or employee of the Department." The Public Rangelands Improvement Act (PRIA) of 1978 (Pub. L. 95-514, Sec. 4, Oct. 25, 1978, 92
2.	Several	The many persuasive arguments against using helicopters to round up wild equines include, but are not limited to, the following: 1. They unavoidably traumatize, terrorize, injure, and kill wild horses. 2. Helicopter roundups also regularly force wild horses –including young foals and elderly or elderly animals– to run from helicopters at dangerous speeds over miles of rugged terrain, causing numerous serious veterinary injuries and fatalities, both during the roundup process itself and following it as a direct result of injuries sustained on these long stampedes. 3. Helicopter roundups also shatter closely knit family bands, forcibly separating foals from their mothers and stallions and mares, terrifying the already frightened animals and destroying the social fabric of wild horse herds.	

No.	Commenter	Comment	BLM Response
		4. They reduce population numbers to genetically unsustainable levels, because the BLM does not use accurate census data and because the agency unfairly skews forage allocations to vastly and unfairly favor privately owned livestock.	Stat. 1805.) also addresses this issue with the direction to "continue the policy of protecting wild free-roaming horses and burros from capture, branding, harassment, or death, while at the same time facilitating the removal and disposal of excess wild free-roaming horses and burros which pose a threat to themselves and their habitat and to other rangeland values." The BLM's helicopter-assisted gathers are conducted humanely, as affirmed by three recent independent reports (see below), and have proven to be more humane, effective, and efficient than other types of gather methods when large numbers of animals need to be removed over wide areas or rugged terrain. Helicopters start the horses moving in the right direction and then back off sometimes one-quarter to one-half mile from the animals to let them travel at their own pace; horses are moved at a more rapid pace when they need to be turned or as they reach the entrance to the capture site. Helicopter pilots are better able to keep mares and foals together than horseback riders; pilots can also more effectively move the animals around such barriers as deep ravines, fences, or roads. In Fiscal Year 2014, out of 1,863 wild horses and burros removed, a total of 18 animals, or approximately one percent (0.97 percent), died or were euthanized during gather

No.	Commenter	Comment	BLM Response
			operations; of those 18, nine animals, or about one-half of one percent (0.48 percent) of the removed animals, died or were euthanized because of acute injuries. Acute injury deaths include all animals that died or were euthanized because of acute injuries, such as spinal cord or head injuries, fractured limbs, or other severe injuries that occurred during gathers. Total deaths include all animals that died or were euthanized for any reason during gathers, including acute or sudden injuries or illnesses, as well as chronic or pre-existing conditions that required euthanasia (such as limb deformities, lameness, and poor body condition). Two reports issued in the fall of 2010 (one by four independent, credentialed equine professionals and one by the Interior Department's Office of Inspector General), plus another report released in 2011 by the American Association of Equine (Veterinary) Practitioners, found -- without any ideological or political bias -- that the BLM's gathers of wild horses are conducted in a humane manner. The Inspector General determined that the BLM's gathers are "justified" and reported that the agency "is doing its best to perform a very difficult job."
ALTERNATIVE METHODS			
3.	Individual	Would like to see grazing permittees exchange livestock AUMs for wild horse AUMs to better manage horse populations since they have expertise and equipment.	The exchange of livestock for wild horse AUMs is outside of the scope of this document.

No.	Commenter	Comment	BLM Response
4.	Several	Several comments were received which recommend alternative population control methods, such as predator management, natural management, and additional facilities.	These suggestions are outside of the scope of this document. Management of predators (wildlife) is outside the authority of the BLM.
5.	Several	Several comments were received which suggest using passive gather techniques such as bait trapping, on the range management bait trapping with volunteers, bait trapping and darting with Native PZP.	The proposed action includes the use of water and bait trapping dependent on herd health and the season (fall, winter, or summer) in which the gather is scheduled in order to maximize gather success and minimize impacts to wild horses. As stated in the EA, the use of bait and water trapping, though effective in specific areas and circumstances, would not be timely, cost-effective or practical as the primary gather method for this HMA due to the size of the area and the remoteness of many of the water sources. During the research part of the proposed action the use of water and bait trapping would not meet the gather objectives to implement the protocols. Water and bait trapping would be used as needed after the research studies are completed.
6.	Several	• Use Field Darting at the Appropriate time of the year (January through early spring), • Recruit volunteer citizen scientists to document the herds to ensure accurate population numbers • Identify band structure and mares to be targeted for fertility control. • Establish follow-up protocol to determine success or failure of the program. • Bait trap to document bands and to apply PZP done by Volunteer Scientists.	See Alternatives Considered but Eliminated from Further Analysis. The population of wild horses on the Conger and Frisco HMAs are over the AML. The water resources and forage within the HMAs cannot support the current number of wild horses. The use of PZP would slow the growth rate

No.	Commenter	Comment	BLM Response
			slightly, reducing the number of horses that need to be removed from the HMAs over time, but would not address the current over population. Remote darting has been shown to be ineffective on wild horse herds in Utah. A study by HSUS on the Cedar Mountain HMA in Utah has shown that after two years of trying to administer PZP through remote darting, not one horse has been darted. The wild horses in Utah (excluding the Onaqui HMA horses) are not use to the presence of people and are very wary. It is extremely difficult to get within 50 yards of the wild horses in the Conger and Frisco HMAs in order to dart them. However, this method would be included as population growth suppression and may be used in the future as one of many tools used in the management of the HMAs.
7.	Several	The EA failed to review, research and implement the Reserve Design strategy for the provision of adequate habitat suitable for long-term viable horse populations. Through appropriate restrictions on area occupied, we would see the "filling of the wild horse niche" and natural self-stabilization of the herd. This is what ecological "climax" species are capable of, given the chance but this requires patience and scientifically supportable research and credibility and common sense – all of which the BLM actions and proposals continually prove they are deficient in.	This suggested management scheme is outside of the scope of this document.
COST OF GATHER			
8.	Several	The EA does not consider the economic impacts of removing wild horses as well as long-term cost and adverse effects of adding	The Wild Free Roaming Horses and Burros Act (WFRHBA) does not require a cost-based

No.	Commenter	Comment	BLM Response
		wild horses to the already overburdened, unsustainable holding pen system.	decision-making process if excess horses are present. "Proper range management dictates removal of horses before the herd size causes damage to the range land (118 IBLA 75)." BLM has a responsibility per the WFRHBA to remove excess wild horses, ensuring the health of wild horses and the rangeland.
NUMBERS OF HORSES GATHERED			
9.	Several	Several comments were received which stated that AML levels should be changed.	This is a planning level decision and is outside of the scope of this document.
10.	Several	Several comments were received which questioned why the BLM proposes to gather horses down and manage at 100 horses in each HMA which is still well above high AML.	See section 1.4 in the Final EA.
11.	Several	Several comments were received which stated that the AML levels were too low to ensure genetic diversity and viability.	See, Section 3.2 Description of Affected Resources, Wild Horses (page 35) of Preliminary EA.
12.	Several	Several comments were received which stated that the population estimates and growth rate of wild horses is inaccurate. These comments are represented by the following.	See Appendix I for the estimated population on the Conger and Frisco HMAs. See section 1.4 in the Final EA.
13.	Cloud Foundation	Wild Horse populations are based solely on estimates that use a 20% annual population growth. Please provide the empirical data to substantiate this growth rate in the Conger and Frisco herds. We find no scientific basis for a 20% growth rate, which is used by the BLM across the board to estimate wild horse populations. Research monies would be better spent on accurately documenting wild horse populations on not only the Conger and Frisco HMAs but on all HMAs and HAs across the country	The Using Science to Improve the BLM Wild Horse and Burro Program A Way Forward published by the National Research Council of the Nation Academies is being used by BLM to develop new procedures and policies in the management of wild horses and burros. Some of the recommendation made by this report have been implemented (ex. population inventory methods) while others are being reviewed or developed within the laws, regulations,
14.	Friends of Animals	BLM's math doesn't add up. The agency states that "approximately 175" wild horses would be removed from the Frisco HMA to maintain an AML of 30-60 wild horses. However, according to BLM's population statistics, there	

No.	Commenter	Comment	BLM Response
		are now 293 wild horses in the Frisco HMA, and if BLM intends to reduce the Frisco population to even the high end of AML, a minimum of 233 wild horses would be removed from the Frisco HMA as a result of the proposed action. Similarly, BLM states that "approximately 225" wild horses would be permanently removed from the Conger Mountain HMA.4 Conger Mountain's population is approximately 342. If BLM intends to reduce the Conger HMA population to an AML of 40-80, the agency would have to remove a minimum of 262 wild horses from the Conger Mountain HMA. Thus, BLM's currently analysis is based on incorrect, confusing, or misleading information.	policies, budgets and other limits that were not considered by the report. However, there is no requirement for BLM to follow or implement any or all of the recommendation made in that report. The BLM utilizes well established scientific methods in the field of range monitoring, inventory and carrying capacity allocations, following approved methods outlined in official technical references and BLM handbooks and manuals. The CCFO and FFO have extensive vegetative trend, utilization, precipitation, actual use, riparian, and rangeland health studies which are contained in the Conger and Frisco HMAs and allotment monitoring files (4120 and 4710 files). Only the most current pertinent information has been summarized within this EA to show that excess wild horses occur within and outside, but adjacent to the HMAs. BLM use population growth rate not Birth Rate. The population inventory that was conducted in February of 2016 used simultaneous double-count method. Photos were taken of each band of horses that were observed. Photos, GPS coordinates and time of recorded observance were used to eliminate from the data any horses or bands that were double counted.
15.	Individual	Per the DOI/BLM herd stats the Frisco HMA wild horse population jumped to 67% in the last year and the Conger HMA wild horse population jumped to 83% last year! See chart below (in the comment letter). This is biologically impossible since mares give birth to only one foal per year at the MOST and stallions and foals (up to reproductive age of about 3 years) do not provide foals and therefore do not add to the annual population. As I stated, this annual population increase is physically unattainable in the wild.	

No.	Commenter	Comment	BLM Response
			According to the NAS 2013 report wild horses are capable of increasing numbers 15-20% annually, resulting in the doubling of wild horse populations about every 3 years.
WILD HORSE AND WILDLIFE IMPACTS			
16.	Return to Freedom Wild Horse Preservation	How many elk, deer and pronghorn graze this HMA? Targeting wild horses for removal to 'protect' the natural resources on the HMA while leaving all these other species on the range will result in continued damage on the HMA.	Management of wildlife is the responsibility of the Utah Division of Wildlife Resource (UDWR) outside the authority of the BLM.
WILD HORSE NUMBERS VS LIVESTOCK NUMBERS			
17.	Several	Several comments were received which stated that livestock numbers should be reduced rather than gather wild horses.	See, Section 3.2 Description of Affected Resources, Livestock Grazing (page 28) of EA. The BLM is not proposing to remove wild horses simply because the population is over AML. Through monitoring and review of other relevant factors, we have determined that excess wild horses are present and need to be removed not only to prevent degradation of the range, but to curtail existing impacts by wild horses and ensure wild horse health and welfare, as well as improvement and health of the habitat. The BLM utilizes well established scientific methods in the field of range monitoring, inventory and carrying capacity allocations, following approved methods outlined in official technical references and BLM handbooks and manuals.
18.	Cloud Foundation	The EA describes the impact of wild horses on every aspect of the environment but fails to consider the even greater impact of livestock grazing. Until EAs evaluate the greater impact of livestock grazing vs wild horse within HMAs and HAs - they have no validity and continue to turn a blind eye to the primary cause of rangeland degradation which is livestock grazing.	
19.	Several	BLM has failed to disclose to the public the actual allocation of forage made available to cattle, sheep, and wild horses in the Conger Mountain and Frisco HMAs.	
20.	AWHPC	At page 41 of the Draft EA, BLM makes the statement that "[o]ver a period of 10 years, competition for forage and water between wild horses, wildlife and livestock would be directly reduced." Given that this project is experimental in design and for the purposes of gathering information on the efficacy of the chosen herd management approach, this statement is appropriately framed as "could be" reduced.	

No.	Commenter	Comment	BLM Response
			Removal of livestock would not be in conformance with the existing Land Use Plan and is contrary to the BLM's multiple-use mission as outlined in the 1976 Federal Land Management and Policy Act (FLPMA) and PRIA, and would be inconsistent with the WFRHBA, which directs the Secretary to immediately remove excess wild horses. Additionally this would only be effective for the very short term as the horse population would continue to increase. Eventually the HMA and adjacent lands would no longer be capable of supporting the horse populations. Livestock adjustments have been made through other actions and documents. The purpose of the EA is not to adjust livestock use. There is no requirement of the WFRHBA or the regulations to reduce or eliminate livestock as a means to restore TNEB. Administration of Livestock grazing on public lands fall under 43 CFR Subpart D, Group 4100. Livestock grazing on public lands is also provided for in the Taylor Grazing act of 1934. The CCFO and FFO have extensive vegetative trend, utilization, precipitation, actual use, riparian, and rangeland health studies which are contained in the Conger and Frisco HMAs and allotment monitoring files (4120 and 4710 files). Only the most

No.	Commenter	Comment	BLM Response
			current pertinent information has been summarized within this EA to show that excess wild horses occur within and outside, but adjacent to, the HMAs. Rangeland Health Assessments were completed on grazing allotments within the gather area from 2007 through 2015 as indicated by the Monitoring Report for the Conger and Frisco HMA. This report showed that causal factors for not meeting standards included, but are not limited to, Pinyon Pine/ Juniper (PJ) encroachment, drought and grazing by livestock, wildlife and wild horses. These studies can be found within the allotment files and summaries of these studies are in the Monitoring Report for the Conger and Frisco HMA. The methodology of each study was completed using technical reference 1734-6. If it was determined that livestock were a causal factor toward the non-attainment of the Standards and Guidelines, changes to livestock grazing were made through the grazing permit renewal process. In the riparian section it states, "Damage to wetland and riparian areas often increases during drought years when wild horses may trample and dig in these areas in search of water. Because many of the springs within the Conger and Frisco HMA are non-functional due to drought conditions, the riparian vegetation is already stressed."

No.	Commenter	Comment	BLM Response
			While this referred to the riparian areas in the HMA in general, there are riparian areas that do not receive use by livestock and those show negative impact by wild horse and wildlife.
IMPACTS OF PERMANENT STERILIZATION ON WILD HORSES			
21.	Several	Several comments were received which stated that the EA did not adequately disclose the impacts to wild horses from permanent sterilization. These comments are represented by the following.	See Proposed Action and Impact Analysis sections in the Final EA. The practice of gelding horses is generally accepted throughout the veterinary community. The research proposal of the propose action is to study behaviors to gelded wild horses in a wild population. This research would then be published to improve BLM's understanding of wild horse demography and behavior to be used in future wild horse management throughout BLM. Other research studies are being conducted on various population growth suppression procedures. There are no genetic, scientific, cultural, or historical resources uniquely present among WH&B. The risks associated with the project are not unique and the risk of gelding alone is well known. The Proposed Action will not establish a precedent for future actions with significant effects or represent a decision in principle about a future consideration. Actions were
22.	AWHPC	There is a substantial question regarding several significance factors; □ Castration of 75% of the male stallions may cause loss or destruction of significant scientific, cultural, or historical resources; □ The use of gelding for wild horse population management is controversial among those in the scientific community. This issue is identified in the Draft EA, but inappropriately dismissed; □ The possible effects of this project are highly uncertain and involve unique and unknown risks; o The very nature of the project as a "research" project indicate that the outcome is unknown. □ The project may establish a precedent for future actions with significant effects; o The very nature of the project as a "research" project indicates the methods and outcomes are intended to be repeated. □ The impacts to the wild horses may result in a violation of federal law.	
23.	AWHPC	The BLM acknowledges the decision to engage in a project that goes against the NAS recommendations (DEA at 5). There is no alternative that included the option of vasectomy rather than castration and indeed, such an alternative was not even considered and later dismissed. This is a violation of the National Environmental Policy Act and renders the analysis in the Draft EA inadequate.	
24.	AWHPC	The BLM must rely upon the best available science when analyzing projects. For this	

No.	Commenter	Comment	BLM Response
		project, the BLM relied on the National Academy of Sciences (NAS) review of the Wild Horse and Burro Program titled "Using Science to Improve the BLM Wild Horse and Burro Program: A Way Forward," June 2013. Unfortunately, as we expressed in our scoping comments, the BLM has apparently used only the portions of the NAS document that support the pre-determined outcome for this project. The NAS findings that did not support the BLM proposal to castrate males from the Conger Mountain HMA were ignored.	considered by the Interdisciplinary Team within the context of past, present, and reasonably foreseeable future actions. Any future projects within the area or in the surrounding areas will be analyzed on their own merits and implemented or not, independent of the actions currently selected. A complete analysis of the direct, indirect, and cumulative effects of the selected alternative, and all other alternatives considered, is described in Chapter 4 of the EA. If significant negative impacts to the animals or rangelands are noted during the studies there would be no reason to repeat or continue the treatments being studied unless the methodology was significantly altered in response to those negative results. If the results turn out to be positive or show no negative impacts than similar work may be repeated elsewhere with some degree of monitoring to make sure the initial results carryover to other HMAs..
25.	AWHPC	The BLM dismisses our concerns about changes to stallion behavior post-gelding by stating that our concerns are unsupported (DEA at 50). However, we again refer the BLM to the NAS findings and recommendations and, indeed, point out that it is BLM's position that is unsupported, by their own admission. Statements in the Draft EA that "BLM fully expects the geldings would remain feisty and unruly with respect to humans" is unsupported by any scientific research.	
26.	Several	BLM is already aware of the impacts of castrating wild horses; the proposed "research study" is unnecessary. The purpose of the Conger Mountain gelding "study project" is to consider the behavioral effects of gelding on wild horse herds.5 BLM states that "[t]his type of information is not currently available."6 However, in 2013 the National Academy of Sciences report on BLM's wild horse program, National Research Council of the National Academies of Science, *Using Science to Improve the BLM Wild Horse and Burro Program, A Way Forward*, (2013)7, ("NAS Report") specifically noted the social and behavioral impacts of castration as a form of fertility control: A potential disadvantage of both surgical and chemical castration is loss of testosterone and consequent reduction in or complete loss of male-type behaviors necessary for maintenance of social organization, band integrity, and expression of a natural behavior repertoire.	
27.	Friends of Animals	So while it does not appear from BLM's horse fatality records that deaths from castration are	

No.	Commenter	Comment	BLM Response
		"rare," an adequate analysis of the actual impacts of surgical gelding requires that BLM provide detailed data regarding the number of horses castrated in BLM facilities per year, and the annual rate of complications, including deaths from evisceration and other causes now listed as "unexplained."	
28.	Several	The BLM must more fully analyze the impacts of the proposed gather, holding, and gelding of males on wild horses and their natural behaviors. The negative impacts of the gelding procedure must be analyzed for individual stallions and on the herd structure and dynamics. Reliance on studies from other areas around the world where herd structure, dynamics, and range are very different is not adequate.	
29.	Cloud Foundation	Gelding Alters Physical Health and Behavior The negative impact of gelding wild stallions has already been demonstrated in the South Steens HMA in Oregon where gelded males have been observed since 2009. Years later, in the South Steens HMA, gelding has had no impact on slowing population growth. Even one intact stallion can service receptive mares in season within the herd area. This is one reason the NAS did not recommend it. Male sterilization is ineffective, expensive, and dangerous.	
30.	Several	Sterilization of male horses causes the loss of male vigor in the stallions and this would have serious disruptive effects upon the individual bands and the surrounding herds to which each band belongs. This would result in less control over the young horses, which could actually result in more reproduction. It has been proven that the mature stable bands produce less offspring and come into balance with available resources. See ISPMB website and also www.thewildhorseconspiracy.org (various articles).	
USE OF POPULATION GROWTH SUPPRESSION			
31.	Several	Several comments were received which support or oppose the use of PZP. These comments are represented by the following.	The proposed action includes the use of population growth suppression using the currently

No.	Commenter	Comment	BLM Response
			approved vaccines and methods and allows for methods that are approved to be used in the future. The proposed action also allows for the use of water and bait traps along with other capture methods to use population growth suppression. These management tools would be used in the Conger and Frisco HMAs to reduce the annual population growth.
32.	Humane Society	We would like to note that some of the assertions regarding treatment with PZP contained within the EA are inaccurate. For instance, the EA notes that the horses in the Conger and Frisco HMAs are unapproachable, and as such a fertility control program using PZP is not feasible. To bolster this argument, the EA states that in the Cedar Mountain HMA, during a study where administration of PZP by remote darting, not a single horse was successfully darted. The EA then rules that because of this, a PZP program is not feasible within the HMA. While it is true that the HSUS study in Cedar Mountain HMA did find that darting horses was not easy, the fertility control program in that HMA was not unsuccessful due to this fact. Because PZP was highly effective in the HMA, more than 70% of the mares were treated in 2012, the 2013 population growth rate at Cedar Mountains was only 4.5%- less than a quarter of normal rates.	The primary use of PZP and any newly approved vaccines or methods would be to maintain the population within AML once achieved. These management tools could be used previous to achieving AML if gather success, holding capacity limitations, population growth rates, other national gather priorities or other circumstances prevent achieving AML during a gather. The population of wild horses on the Conger and Frisco HMAs are over the AML. The use of PZP would slow the growth rate slightly, reducing the number of horses that need to be removed from the HMAs over time, but would not address the current over population. Remote darting has been shown to be ineffective on wild horse herds in Utah. A study by HSUS on the Cedar Mountain HMA in Utah has shown that after two years of trying to administer PZP through remote darting, not one horse has been darted. The population growth

No.	Commenter	Comment	BLM Response
			rate on the Cedar Mountain HMA was reduced after gathering the population and administering PZP-22 on two separate occasions. The wild horses in Utah (excluding the Onaqui HMA horses) are not used to the presence of people and are very wary. It is extremely difficult to get within 50 yards of the wild horses in the Conger and Frisco HMAs in order to dart them. However, this method would be included as fertility control and may be used in the future.
DATA USED			
33.	Several	Several comments were received which questioned the data used in the analysis. These comments are represented by the following.	The BLM is not proposing to remove wild horses simply because the population is over AML. Through monitoring and review of other relevant factors, we have determined that excess wild horses are present and need to be removed not only to prevent degradation of the range, but to curtail existing impacts by wild horses and ensure wild horse health and welfare, as well as improvement and health of the habitat. The BLM utilizes well established scientific methods in the field of range monitoring, inventory and carrying capacity allocations, following approved methods outlined in official technical references and BLM handbooks and manuals. The CCFO and FFO have extensive vegetative trend, utilization, precipitation, actual use, riparian, and rangeland
34.	Individual	Horses are designated as “wild” under the FRWHBA. They do not compete with wildlife, They are wildlife. They are not designated livestock with cattle. Livestock are continually left out of the equation when assessing damage or reduction of forage and blame laid only on the horses.	
35.	Individual	The EA states that the "Key Forage" method was used to evaluate range-conditions. The full title of that approach is the "Key Forage Plant" (KFP) method. However, KFP is obsolete, having been replaced by the Landscape Appearance method as far back as 1996. Moreover, per Technical Reference 1734-7, Ecological Site Inventory, such qualitative assessments "may result in reduced accuracy, limiting use of the data." If for only this reason, I cannot rely on the EA's representations regarding conditions in the Conger and Frisco HMA.	

No.	Commenter	Comment	BLM Response
			health studies which are contained in the Conger and Frisco HMAs and allotment monitoring files (4120 and 4710 files). Only the most current pertinent information has been summarized within this EA to show that excess wild horses occur within and outside, but adjacent to the HMA. Rangeland Health Assessments were completed on the grazing allotments within the gather area from 2007 through 2015. Causal factors for not meeting standards included, but are not limited to, Pinyon Pine/Juniper (PJ) encroachment, drought and grazing by livestock, wildlife and wild horses. These studies can be found within the allotment files and summaries for the Conger and Frisco HMAs. The methodology of each study was completed using technical reference 1734-6. If it was determined that livestock were a causal factor toward the non-attainment of the Standards and Guidelines, changes to livestock grazing were made through the grazing permit renewal process. In the riparian section it states, "Damage to wetland and riparian areas often increases during drought years when wild horses may trample and dig in these areas in search of water. Because many of the springs within the Conger and Frisco HMAs are non-functional due to drought conditions, the riparian vegetation is already stressed". While this referred

No.	Commenter	Comment	BLM Response
			to the riparian areas in the Conger and Frisco HMAs in general, there are riparian areas that do not receive use by livestock and those show negative impact by wild horses and wildlife.
36.	Individual	A list of all range improvements done to manage and protect wild horses including, but not limited to, a list of all water sources, year-round availability of these water sources to wild horses and other wildlife	Not all data used to determine excess wild horses is contained within the EA. The purpose of the EA is to document the potential impacts associated with the Proposed Action and alternatives. Including this data in the EA would be cumbersome and would not change the impact analysis. Additional information is available at the BLM Fillmore and Cedar City Field Offices. The CCFO and FFO have extensive vegetative trend, utilization, precipitation, actual use, riparian, and rangeland health studies which are contained in the Conger and Frisco HMAs and allotment monitoring files (4120 and 4710 files). Only the most current pertinent information has been summarized within this EA to show that excess wild horses occur within and outside, but adjacent to the HMA. Added latest population inventories as an appendix to Final EA.
37.	Individual	Current and twenty-year historical documentation of herd population count/census numbers and a complete demographic breakdown of the Frisco and Conger wild horse populations (number of bands, stallion/mare ratio, number of foals, yearlings, two year olds and aged horses) including application, impact and results of past contraceptive use on the wild horses.	
38.	American Wild Horse Preservation	The EA failed to provide adequate alternative actions and fails to disclose or analyze the following prior to selecting the proposed action: • Rangeland assessment reports and results (and full assessments should be provided in the Appendix) for each the past five years for all areas in the HMA (including pastures, allotments, etc) – including all rangeland assessments used for the renewal of livestock permits, annual actual use of permitted livestock AUMs for each of the past five years (to better understand the cumulative impacts of livestock grazing on the HMA rangeland health), etc. • Methodology used to differentiate livestock usage impacts from wild horse impacts. Map of year-round and seasonal water sources within the HMA and a detailed description of all BLM actions (years, actions, locations) to protect and develop water sources. • Disclosure of the data utilized to determine the establishment of AML for the HMA and whether the conditions have changed	

No.	Commenter	Comment	BLM Response
		which would follow NAS recommendations of utilizing Adaptive Management to reassess AMLs in the EA. Include a complete list of all interested parties consulted when establishing AML and all scientific data used to set AML. • Mapping depicting the location of the wild horses in and outside the HMA, fence lines and water sources and all census data regarding the number of the wild horses.	
COMPLIANCE WITH POLICY			
39.	Individual	The EA fails to consider an alternative that includes working with wild horse advocacy organizations to re-evaluate and address the woefully inadequate Comprehensive Animal Welfare Program (CAWP) that pertains to the treatment of wild horses and burros during and after roundups as attached to this EA.	Considering alternatives to the Comprehensive Animal Welfare Program (CAWP) is outside the scope of this document. The CAWP policy is a national policy, not specific to the actions taken associated with the Conger and Frisco HMA. Fillmore and Cedar City Field Offices will follow the most current BLM policies pertaining to the CAWP. Minimal feasible level references the minimal level of management actions used to achieve Land Use Plan objectives, which the proposed action complies with.
40.	Several	Removing wild horses from the range, castrating them, and warehousing them in permanent holding facilities is not the "minimal feasible level" of wild horse management required under the Free-Roaming Wild Horses and Burros Act (WHBA), and the costs of doing so is an impact that must be disclosed under the National Environmental Policy Act (NEPA).	
COMPLIANCE WITH NEPA			
41.	AWHPC	This project presents a 10-year plan, using new research methods, over two HMAs, covering more than 200,000 acres of land. The length of the Draft EA alone suggests that an Environmental Impact Statement would have been more appropriate. Given the large amount of land covered, the large number of horses to be gathered and/or treated, and the current conditions on the ground, the BLM should conduct a more thorough analysis of the impacts of the proposed research project using an Environmental Impact Statement.	The analysis contained in the EA did not result in the expectation of any significant impacts to the human environment; consequently, an environment impact statement is not required. Please see the FONSI associated with the EA.

No.	Commenter	Comment	BLM Response
42.	Individuals (Chain)	The BLM should prepare an Environmental Impact Statement and cannot proceed on a Finding of No Significant Impact. The proposal to geld stallions as part of a research project to determine the efficacy of gelding as a population management tool has not been proven, is highly controversial, and will have significant impacts on the wild herd. All the impacts of this proposed action are not well understood, are uncertain, and are likely to be extremely detrimental to the well being of these wild horses. Further, the National Academy of Sciences already has clearly delineated the fundamental impacts of castration on wild stallions, stating that it will cause "loss of testosterone and consequent reduction in or complete loss of male-type behaviors necessary for maintenance of social organization, band integrity, and expression of a natural behavior repertoire.	
43.	AWHPC	The impacts to the wild horses may result in a violation of federal law.	The WFRHBA identifies sterilization as a means of population control. It also allows removals and research in the management of wild horses and burros.
44.	AWHPC	Tiering this Draft EA to the 1987 Warm Springs RMP and the 1983 Pinyon MFP is inadequate not only because those documents do not specifically address the type of research proposed and do not identify impacts specific to these two HMAs, but they are also both extremely outdated, 29 and 33 years old, respectively. Reliance on these documents and the extremely outdated analysis contained in both is inappropriate. Issues related to climate change, recent decades of drought, the American public's opinion on wild horses, and modern grazing practices are not included in those documents.	Any changes in the affected environment which have occurred since completion of these land use plans were considered in the EA. Projects do not need to be specifically addressed in a land use plan to be in conformance with the goals, objectives and decision of the land use plan.
GENETIC DIVERSITY			
45.	Several	Several comments were received concerning the loss of genetic diversity or viability. These comments are represented by the following.	See the Proposed Action and section 3.0 of the Final EA.
46.	Friends of Animals	BLM should consider the effect of this proposal on the genetic viability of the Frisco and the Conger Mountain herds. Under Alternatives 1	

No.	Commenter	Comment	BLM Response
		and 2, BLM proposes to subject both herds to repeated removals to reduce the population to dangerously low levels: the Frisco AML is 30-60, and the Conger Mountain AML is 40-80.23 In addition, up to 75% of the few Conger Mountain stallions released to the HMA will be subject to castration under alternative 1.	
47.	Cloud Foundation	Alternative 1 threatens genetic viability. (P 35 EA). According to the EA Hair Samples for genetic testing were collected and analyzed in 2012 by D. Gus Cothran. Dr. Cothran's analysis of the Frisco HMA states that "in general genetic viability is on the high side but there's a high percentage of variation at risk. Cothran's 2009 analysis of the Conger HMA states "if at any time in the future the genetic diversity is determined to be relatively low, a large number of the HMAs could be used as a source of fertile horses to be transferred to Conger HMA.	
RESEARCH			
48.	Several	Several comments were received which expressed concern with the use of radio collars. These comments are represented by the following.	Based on numerous studies that have used modern radio collars with remote releases and tags to study the ecology of wild ungulates and equids in particular, these devices have minimal effects on the animals wearing them. The impact of radio collars and tags is very minimal. From March 2015 through March 2016 researchers at the U.S. Geological Survey conducted a preliminary study on captive wild horses and burro jennies to determine proper fit and wear of radio collars (Schoenecker et al. 2014). The condition of wild horses wearing radio collars was compared to non-collared controls and documented with photographs. In addition, both collared individuals and controls were observed for 80 minutes each week for 14
49.	AWHPC	The EA/EIS must disclose and analyze all details of BLM data, information and research that resulted from implementing radio collar research on wild horses in Nevada in the 1980s and other BLM radio collar projects. The EA/EIS must disclose and analyze that BLM-sourced data – including the resulting harm that occurred to the collared horses, deaths, euthanasia, etc.	
50.	AWHPC	The EA/EIS must address how such deleterious effects of neck radio collaring of mares will be addressed or prevented given that mares also move their necks in manners that may allow the collar to become imbedded in the neck tissue, get caught on forage or fencing, be bitten by other horses, and cause discomfort or injury to the horse.	
51.	AWHPC	The fluctuating body condition of mares based on season, and the growth of younger mares as they mature must also be considered. The EA/EIS must consider and disclose the reason radio tail trackers are not used in mares as they	

No.	Commenter	Comment	BLM Response
		are proposed to be used on stallions. The EA/EIS must take a hard look at existing scientific data that outlines natural wild mare movements, behaviors, activities that may or likely will cause radio collars to move and tighten on the mares' necks.	weeks in order to quantify any impact of the collar on their behavior and health. At the end of the study period (March 2016) the collars were removed. Preliminary analyses indicate that mares had almost no impact in terms of rubbing or wear from radio collars, and behavior of collared and uncollared mares did not differ (Schoenecker et al. 2016 in prep). There was no impact of radio tags on behavior or wear, either. The reason collars are being used for mares instead of tail tags is because the retention of tags on the individual horse is shorter than collars, and the battery life for collecting data is shorter for tags than collars. The use of field observers and individuals to track and monitor wild horses on the ground, would not be time effectively, cost-effective or practical as the primary monitoring method for this HMA due to the size of the area, and the remoteness of many of the horses and large number of horses involved. However, some of this monitoring of unmarked horses would occur with the help of the collars and tags to help locate the animals. Also, locating wild horses by ground observers has flaws in terms of the scientific study design. With radio collars/tags, individually marked horses can be located using a randomized design, instead of "whenever the observers happen to find them." The latter method
52.	AWHPC	While the BLM may want to cite that "radio collar technology has been in regular use in other ungulate species for over 40 years" as a rational for the proposed experiment of putting neck radio collars on mares, the EA/EIS must provide scientific rational how this radio collar technology in "other ungulate species" applies to wild mares.	
53.	AWHPC	The EA/EIS must disclose and analyze any available data, reports, communications, etc. available within the various BLM offices related to wild horse and/or burro neck radio collar projects/pilots/programs/research which has occurred during the course of the agency's history of managing wild horses and burros. The implications of behavioral change to such individuals and deleterious effects of the neck radio collars must be disclosed and analyzed.	
54.	AWHPC	The EA/EIS must include as an appendix the results of radio collar research recently conducted by USGS at the BLM's Pauls Valley holding facility in Oklahoma.	
55.	AWHPC	The EA/EIS must disclose and analyze all details of BLM data, information and research that resulted from implementing radio collar research on wild horses in Nevada in the 1980s and other BLM radio collar projects. The EA/EIS must disclose and analyze that BLM-sourced data – including the resulting harm that occurred to the collared horses, deaths, euthanasia, etc.	
56.	AWHPC	Page 12 of the Draft EA indicates that pre-treatment behavior data will be collected on 16 tagged males and 4 collared females and their associates between March and September 2017. Please provide additional details regarding the collection of data. How often will horses be observed and for how long?	
57.	AWHPC	Page 12 of the Draft EA indicates that in "consultation with BLM specialists" a decision to geld 50-75% of all adult males in the	

No.	Commenter	Comment	BLM Response
		population was made. However, there is no evidence or information in the Draft EA or associated appendices that provides the public with an opportunity to review this "consultation" and provide feedback.	introduces bias into the study design and ultimately, the resulting data.
58.	AWHPC	Page 13 of the Draft EA indicates that males will be randomly selected for gelding. What procedure is the BLM utilizing to ensure that genetically valuable males are not gelded?	
59.	Individual	The BLM also fails to provide specific information concerning the disastrous attempt to conduct studies using radio collars on wild horses from Nevada in the 1980s which resulted in great harm to the collared "research" subjects including deaths and euthanasia. The data resulting from this botched "research" endeavor must be provided and thoroughly analyzed to ensure no such debacle endangers or kills federally-protected equines in any future "research studies" including the present proposed action.	
60.	Individual	Furthermore, prior to initiating this research study, I must insist that the results of radio collar research recently conducted by USGS at the BLM's Paul's Valley holding facility in Oklahoma be reviewed and disclosed as part of any Environmental Assessment (EA). Also, the results of the radio collar research conducted in the 1980's on Nevada wild horses should be included in any EA: injuries, death, foals orphaned, all pertinent data; so those mistakes will not be repeated in any research going forward.	
61.	Individual	Present your plan - how are you going to separate the stallions from their bands, transport them, treat their injuries from being transported together, and how are you going to tag them.	
GENERAL			
62.	Several	Several comments were received which expressed general support or opposition to the gather, but did not contain substantive information.	Several comments recommended changes in policy or actions which are outside of the scope of this EA.

No.	Commenter	Comment	BLM Response
63.	Individual	As required by regulation [43 CFR 4740.1(b)], a public hearing was held in Price, Utah on December 8, 2015 and will be held in subsequent years to discuss the use of helicopters and motorized vehicles in the management of Utah BLM's wild horses and burros. ... Comments received from the Preliminary Environmental Assessment (EA) and at those public meetings will be considered and, if applicable, will be addressed in management actions, NEPA documents, and decision documents using the most current direction from the National Wild Horse and Burro Program. EA pdf-page 44 I submitted detailed, substantive comments for the hearing. By now, BLM should have acted upon them and made reforms.	These comments were considered but will not be addressed specifically in this document. The comments and reforms received at the public meeting in Price on December 8, 2015 had to do with national policies and actions. They have been passed onto the national program by the Price Field Office.
64.	AWHPC	The first two paragraphs of the Draft EA at page 31 appear to be contradictory. The first sentence of the first paragraph states that BLM Standards and Guidelines for Healthy Rangelands "were not being met," while the first sentence of the next paragraph states these same guidelines are being met. Please explain this contradiction.	The first paragraph is referring to the Frisco HMA and the second is referring to the Conger HMA.
65.	AWHPC	It does not appear that the BLM has read or responded to the expert declarations of Dr. Anne Perkins, Dr. Allen Rutberg, Dr. Jay Kirkpatrick, and Dr. Bruce Nock, submitted with our scoping comments. The BLM must review these declarations and incorporate this information into the analysis for this project.	These individuals comments and opinions contained in these declarations were reviewed and address where appropriate within the impact analysis section of the EA.
66.	Individual	Questions about Procedures a) it isn't clear if you are comparing frisco to conger with frisco as the control group b) in frisco you tag 20 adult males, 40 adult mares, and 15 yearling; in conger, on the other hand, you tag 30 adult males and 30 adult mares; in conger you also tag 8 treated, 8 untreated males and 4 mares to do your gelding studies c) observations on animals targeted for gelding studies are unspecified but later in your ea you speak to observing if geldings form bachelor bands or intermix with harem bands, band sizes, gelding distribution in the habitat, and	See Section 1.4 Purpose of the Proposed Action in Final EA.

No.	Commenter	Comment	BLM Response
		utilization and activities around water sources.	
67.	Individual	The EA states that the study-results will also be used to update WinEquus, a population-projection software program. However, WinEquus evidently has internal programming errors that yield contradictory and even impossible predictions. A product that is broken must be fixed before it can be updated; but fixing WinEquus is not part of the study.	Out of scope of this document.
68.	Individual	This proposal includes releasing the wild horses back to the herd areas, but you have not especially addressed the mares and foal pairs. Will those be returned?	See Proposed Action in Final EA.
69.	Individual	You also do not make provisions for how close the horses will be returned to their home areas and in what band configuration.	See Proposed Action in Final EA.
70.	Individual	The public must be provided with information showing a complete and detailed breakdown of water allocations, which include multiple use projects such as: % of water allocated to mining projects % of water allocated to gas/oil explorations/ extractions % of water allocated to wind projects % of water allocated to solar projects % of water allocated to geothermal projects % of water allocated to other multiple use projects % water allocated to Livestock % water allocated to Wildlife % water allocated to Wild Horses and/or Burros	This information is not necessary for the analysis of environment impacts included in this document.

APPENDIX H

Procedure for Affixing Radio Collars on Wild Horse Mares and Burro Jennies

Introduction

The purpose of this document is to provide detailed methods that will be used for fitting radio collars on wild horse mares and burro jennies. This document does not include methods for chemical immobilization, care and maintenance of horses during gathers, while in captivity, or for any other handling procedures beyond those needed for fitting a radio collar.

The study of animal behavior and ecology requires understanding the daily life of the focal species (King 2013). It is now common to use radio collars fitted with VHF transmitters, GPS recorders, or satellite transmitters to obtain and record data on movement and other activities. While most radio collars are considered to be minimally invasive, they can impose a cost on the animal carrying them. Thus guidelines have been developed for a weight ratio (a collar should not exceed 5% of the animal's body weight) and best practice in their use (Ministry of Environment, Lands and Parks Resources Inventory Branch for the Terrestrial Ecosystems Task Force Resources Inventory Committee 1998, Sikes et al. 2011). Collars have the potential to cause injury to the animal wearing them. However when the collar is fitted correctly and monitored regularly it can provide invaluable data without any measureable impact on the study animal.

Telemetry collars have been used extensively on carnivores (Germain et al. 2008, Creel and Christianson 2009, Hunter et al. 2010, e.g. Broekhuis et al. 2013, Cozzi et al. 2013, Dellinger et al. 2013), rodents (Chambers et al. 2000, Solomon et al. 2001, Koprowski et al. 2007), and some ungulates (Johnson et al. 2000, Creel et al. 2005, Ito et al. 2005, Allred et al. 2013, Buuveibaatar et al. 2013, Latombe et al. 2013), however they have not been commonly used on equids. A few studies have used this tool to examine habitat use, movements, and behavior of zebra (Fischhoff et al. 2007, Sundaresan et al. 2007, Brooks and Harris 2008) and Asiatic wild asses (Kaczensky et al. 2006, 2008, 2011). Even fewer published studies have used telemetry collars on feral horses (Committee on Wild Horse and Burro Research 1991, Asa 1999, Goodloe et al. 2000, Hampson et al. 2010).

Although some research has been conducted on wild horse use of vegetation and habitat (e.g. Beever and Brussard 2000), little has been done recently, and long-term, fine-scale data on habitat use has never been gathered. Yet it is important that resource managers have a scientifically based understanding of wild equid seasonal habitat use and movements on public lands. Due to the scale of some of the Herd Management Areas (HMAs) it is logistically challenging to collect habitat use data via direct observation. Utilization of GPS and VHF collars for marking and locating individuals will provide fine-scale data about where wild horses spend their time and how they use their habitat.

From March 2015 through March 2016 researchers at the U.S. Geological Survey conducted a year-long preliminary study on captive wild horses and burro jennies to determine proper fit and wear of radio collars (Schoenecker et al. 2014). The condition of wild horses wearing radio collars was compared to non-collared controls and documented with photographs. In addition, the behavior of both collared individuals and controls was recorded for one hour daily, in order to quantify any impact of the collar on their behavior and health. At the end of the study period (March 2016) the collars were removed. At this time data are being analyzed and written up for submission to a peer reviewed journal (Schoenecker et al. 2016 *in prep*).

Radio collars consist of a 2-inch wide strap/belt made of soft pliable plastic-like material (Figure 1). Some are oval shaped with adjustments on both sides of the collar, and others are teardrop shaped with adjustments at the top of the collar so it can be fitted to different neck sizes. This is the most optimal

shape for the neck of equids. Attached to the belt of the collar is a battery pack and transmitter module. These may either be combined in the same unit, or placed at the top and bottom of the collar to counterbalance each other. The size of the battery is determined by the amount of power needed, both in terms of length of deployment, and how much data will be recorded by the collar. The type of transmitter used will depend on the study, but all principles stated here for collar fitting and use apply regardless of communication systems used.

Collars can be placed on horses' necks when wild horses are in a padded squeeze chute during a gather. It takes between 7 and 12 minutes to fit a collar on the animal. The transmitter should be functioning and turned on before the collar is fitted, then checked that it is working correctly before the animal is released.

Fitting of the collar

Fitting a collar on an equid requires an understanding of the neck circumference and shape; that is, when the head of the animal is raised the collar should be tight, and when the head is down grazing the collar will become looser (Figures 2, 3). The collar should rest just behind the ears of the equid and be tight enough so it does not slip down the neck, yet loose enough that it does not interfere with movement when the neck is flexed. The collar must fit snugly to minimize rubbing. USGS researchers used 0-1 finger between collar and neck, depending on season collar is deployed to give consideration to the potential for weight gain. Other studies (e.g. Committee on Wild Horse and Burro Research 1991) have had problems with the fitting of collars due to animals gaining weight in spring, or losing weight in winter, causing collars to become too tight or too loose. In the USGS study, researchers did notice collars were looser or tighter at different times during the year, but it did not affect the behavior of collared mares or jennies, or cause sores or wounds on mares or jennies. Whenever collars are deployed they should be fitted by experienced personnel who can attach the collar quickly but proficiently to minimize handling stress on the animal.

Figure 1. Two collar designs to use on wild horses and burros; one is teardrop shaped, and the other is oval shaped from Collins et al. (2014).

Figure 2. Burro jenny fitted with a radio collar in the USGS study showing appropriate placement of collars higher on the neck, behind ears.

Figure 3.Wild horse mares fitted with radio collars in the USGS study showing head up and head down, and demonstrating appropriate placement of collars higher on the neck just behind the ears.

Date: 20 May 2016
RE: Statistical analysis for 2016 horse population surveys in Utah

I. Summary Table

HMAs and Dates*	February 8, 2016	Frisco HMA	(UT0445)
	February 9, 2016	Conger HMA	(UT0553)
	February 10, 2016	Sulphur HMA	(UT0448)
	February 11, 2016	Sulphur HMA	(UT0448)
	February 12, 2016	Sulphur HMA	(UT0448)
Type of Survey	Simultaneous Double-observer		
Aviation Company	Cody J (pilot), El Aero Services, Bell 206B3 (N8052G)		
Agency Personnel	Chad Hunter, Eric Reid (BLM), Kate Schoenecker (USGS), Levi Anleers (BLM helicopter manager)		

*HMAs are listed for any day on which they were surveyed, and any day on which an animal found outside the HMA boundaries was closest to that HMA.

Table 1. Estimated population sizes (Estimate) are for the numbers of horses in each surveyed area at the time of survey. 90% confidence intervals are shown in terms of the lower limit (LCL) and upper limit (UCL). The coefficient of variation (CV) is a measure of precision; it is the standard error as a percentage of the estimated population. Number of horses seen (No. Seen) leads to the estimated percentage of animals that were present in the surveyed area, but that were not recorded by any observer (% Missed). The estimated number of horses outside each HMA, is already included in the total estimate for that HMA.

Area	Age Class	Estimate (No. Horses)	LCL [a]	UCL	Std Err	CV	No. Horses Seen	% Missed	Estimated # of Groups	Estimated Group Size	Foals per 100 Adults	Est. No. Horses Outside HMA
Frisco HMA	Total	288	257	373	34.8	12.1%	245	14.9%	69	4.2	11.2	136
	Foals	29	24	39	4.1	14.1%						
	Adults	259	233	334	31.7	12.2%						
Conger HMA	Total	310	270	347	23.5	7.6%	285	8.0%	44	7.1	19.1	0
	Foals	50	42	58	4.5	9.0%						
	Adults	260	229	292	19.8	7.6%						
Sulphur HMA	Total	1097	1025	1269	71.5	6.5%	958	12.7%	191	5.7	22.0	340
	Foals	198	182	232	14.6	7.4%						
	Adults	899	837	1034	58.4	6.5%						

[a] 90% confidence interval based on percentiles of bootstrap simulation results. The lower 90% confidence interval limit (LCL) is actually less than the number of animals sighted during the survey for some estimates. This is a normal statistical result and reflects the fact that a confidence interval expresses what would likely happen if the survey were repeated. If repeated many times, some surveys would miss more animals and produce lower estimates, even after corrections, than were actually observed during this survey. Clearly, I conclude that there are at least as many animals as were observed during this survey, rather than using the lower confidence limit as a minimum number.

II. Narrative

In February 2016, Bureau of Land Management (BLM) personnel conducted simultaneous double-observer aerial surveys of the wild horse populations in the Frisco, Conger, and Sulphur herd management areas (HMA) in Utah (Figure 1). Surveys were conducted using survey methods recommended by BLM policy (BLM 2010) and a recent National Academy of Sciences review (NRC 2013). I analyzed these data to estimate sighting probabilities for horses, which I then used to correct the raw counts for systematic biases (undercounts) that are known to occur in aerial surveys, and to provide confidence intervals (which are measures of uncertainty) associated with the estimated population sizes.

Population Results

The estimated total horse populations (Table 1) within or associated with the HMAs that were the focus of the surveys were relatively small at Conger HMA and Frisco HMA, but higher at Sulphur HMA, resulting in a sample size of 269 horse groups (Table 2, Figure 1) of which 216 horse groups had data recorded in a way so that they were suitable to be used in estimating statistical estimates of sighting probability. All 269 observations made during 2016 aerial surveys were used to inform the total estimates of population size. Confidence intervals and coefficients of variation are within acceptable levels of precision for management purposes (Table 1).

I estimated the mean size of detected horse groups, after correcting for missed groups, to be 5.6 horses/group across surveyed areas with a median of 4 horses/group. I note that the detected groups may have been composed of more than one social band. I estimated a composition of 19.5 foal horses per 100 adults at the time of these surveys, but this number is a reflection of the winter season of the surveys and should not be interpreted as an indication of foaling rate for 2015 or 2016.

Sighting Probability Results

The front observer saw 77.2% of the horse groups (81.0% of the horses) seen by any observer, whereas the back seat observers saw 72.6% of all horse groups (76.5% of horses) seen (Table 2). These results demonstrate that simple raw counts do not fully reflect true population size, without statistical corrections for missed groups made possible by the double observer method and reported here.

Informed by *a priori* reasoning, past analyses, and preliminary analyses I considered 64 alternative models. In all of these alternatives, I included an intercept and 5 additional parameters for the effects of: (1) front seat observers when a horse group was visible on both sides of the flight path, (2) back seat observers when a horse group was located directly on the flight path and not visible to either of them, (3) horse group activity (movement), (4) percent vegetation cover, and (5) observer position in the back seat. All of these parameters received overwhelming support in preliminary analyses. In addition to these 5 parameters included in all models, I considered the 64 models with all possible combinations of 6 additional covariates believed *a priori* to be likely predictors of sighting probability: (1) an additive effect for front observers' sighting probability for groups located on the pilot's side of the flight line, (2) horse group size, (3) rugged terrain, (4) snow cover percent and snow cover percent squared (both covariates or neither), (5) distance from the flight transect to the group, and (6) presence of high contrast lighting.

Of the 6 covariates tested, support (% of AIC_c model weight) was highest for the effect of

distance (77.2%). The other 5 effects tested all had weak support ranging from 27.1%-31.5% AIC_c model weight. As expected, estimated sighting probability was higher for groups that were: visible to both front seat observers, larger, active, or closer. Horses groups on the pilot's side and in the back for groups on the centerline were less visible. Also as expected, vegetation cover and high contrast lighting conditions reduced visibility. Sighting probability was also slightly higher for back-seat observers for groups on the primary observer's side of the aircraft (i.e., not the pilot's side, center, or both sides). The effect of snow cover was reduced visibility for intermediate levels of snow cover than for none or complete cover; in other words, patchy snow conditions reduced visibility as expected (Table 3).

The estimated sighting probabilities for the combined observers ranged across horse groups from 41.2%-100%. Sighting probability was lower than desirable for many horse groups. There were 25 groups (9.7% of all observed groups) with sighting probability <70% for the combined front and back observers and another 25 with sighting probability between 70-80%. Vegetation cover and patchy snow conditions were the primary factors resulting in these lower estimates. Note that the baseline case in Table 3 is for horses that were not moving and were ¼ - ½ mile from the observer, leading to the relatively low sighting probabilities indicated. However, most groups (151 groups, 69.9%) were moving and some (26 groups, 12%) were closer to the observers, so the average sighting probability (88.3%) was, in fact, much higher.

Comparing actual horses seen to the estimated population size computed from the estimated sighting probabilities, I estimate that 12.2% of the horses in these surveys were never seen by any of the observers (Table 1). The wide range of sighting probabilities were a result of diverse conditions with vegetation cover contributing the most to variability, followed by group activity, distance, and snow cover. Group size was as high as 33 horses. There were 32 observed horse groups with >10 horses (12.4% of groups containing 33.0% of the horses), however the effect of group size in sighting probability was small relative to other effects.

Assumptions and Caveats

Given several potential sources of bias, listed below, it is more likely that the estimates are somewhat lower, rather than higher, than the true population. The high sighting probabilities and precision estimated for these surveys, the population estimates I present here appear to provide a sound and reliable basis for management decisions. Although the sample size available for this analysis was adequate, a larger survey would provide additional information about sighting probability and increase confidence in the results.

The reliability of results from any population survey that is based on the simultaneous double-observer method rests on several important assumptions. First, the results obtained from these surveys are estimates of the horses present in the areas surveyed at the time of the survey and should not be used to make inferences beyond this context. I must presume that pre-flight planning by the district specialist and the BLM aerial survey coordinator led to the surveyed areas including as much as possible of the areas used by each population of horses using the surveyed HMAs. Although fences and topographic barriers can provide deterrents to animal movement that help to contain them within the areas surveyed, these barriers may not present either a continuous, unbroken barrier or an impenetrable one. However, the surveys did not necessarily extend as far beyond the boundary as horses might move. Consequently, it is possible that temporary emigration from the surveyed areas may have contributed to some animals of a

given population not being present in the surveyed areas and the numbers of animals found within the survey areas at another time could differ substantially.

Second, the validity of the analysis rests on the assumption that all groups of animals are flown over once during a survey period, and thus have exactly one chance to be counted by the front and back seat observers, or that groups flown over more than once are identified and considered only once in the analysis. Groups counted more than once would constitute 'double counting,' which would lead to estimates that are biased higher than the true number of groups present. The Conger and Frisco surveys were each completed on a single day, which should have helped to reduce the risk of double counting for these locations. The identification of 'marker' horses (horses with unusual coloration) in each group was recorded on paper, and variation in group sizes probably helped the observers to reduce the risk of double counting during aerial surveys. Observers also took photographs of almost every group, and used those photos after landing to identify any groups that were inadvertently recorded twice. Additionally, groups that were never available to be seen (for example, due to temporary emigration from the study area or due to moving, undetected, from an unsurveyed area to one already surveyed) can lead to estimates that are negatively biased compared to the true population size. Given the tendency of horses in these populations to run from the approaching helicopter, this is a significant concern.

Third, this method assumes that all horse groups with identical sighting covariate values have equal sighting probability. If there is additional variability in sighting probability not accounted for in the sighting models, such heterogeneity could lead to a negative bias (underestimate) of the population. Low sighting probabilities for horses in some situation leave open the possibility that other factors not considered could result in variation in actual sighting probabilities that are not fully modeled. Horses that were unavailable because they ran from the approaching helicopter before they could be seen would certainly contribute to heterogeneity and a negative bias in the estimates.

A fourth assumption is that the number of animals in each group is counted accurately. In very large groups it may be common to miss a few animals unless photographs are taken and scrutinized after the flight. Relying on raw counts made from a helicopter could lead to biased low estimates of population size. Observers in this survey, though, circled over large groups to get as accurate a count as possible and used photography on nearly all groups, thereby minimizing the risk of undercounting group size.

Recommendations for Future Surveys

This survey was well designed and generally followed the specified protocols. Nevertheless, several observations about the data may offer opportunities to improve future surveys.

1. Increasing sighting probability increases precision of the population estimates. To achieve higher sighting probabilities, it is best to time surveys so that snow cover is either absent or nearly 100%, to the extent possible. Flying more slowly over vegetated areas and patchy snow would also help address this problem, as would tighter transects in areas with these conditions (see below). In addition, slowing or circling while observers photograph groups and record data could also contribute to higher sighting probabilities.
2. Predefined transect spacing varied from approximate 0.5-1.0 miles. The pilot flew these as planned most of the time, although the flight path deviated from the plan in a few locations, leaving larger gaps between transects than desired. In most portions of the survey area the spacing was appropriate for the conditions, however, there were a few

gaps in the vegetated mountains that were >0.5 miles. Spacing in the unvegetated, flat valleys was probably tighter than necessary, given the high estimates sighting probabilities for these conditions. Increased spacing in open areas to 1.5 miles and better coverage with consistent 0.5 mile spacing in more rugged, vegetated terrain would improve sighting probability and reduce error at roughly the same cost.

3. Observers reported (Kate Schoenecker and Chad Hunter, pers. comm.) that horses were frequently running in response to the approaching helicopter. This makes it more likely that some groups will run into areas not yet surveyed and be double counted, while other run before detection into areas already surveyed and have no chance of being detected. Although photographs were used to effectively reduce or eliminate the double counting problem, there is no effective way after the survey to correct for the converse problem of horses fleeing and evading observations entirely. Participants in this survey have already conferred and made changes to the planned transects for future surveys that are intended to reduce the likelihood that horses will run toward areas already surveyed and thus never be available to observers.

4. In 18 instances, a horse group was observed by both back seat observers even though the side of ship was not recorded as "both". Of these, 8 instances were marked as not following protocol, leaving 10 cases with this anomaly in the analysis. Observers reported (Kate Schoenecker, pers. comm.) that these groups were first seen on one side and then ran across the flight path and became visible on the other side as well. The side of ship where they were first seen was recorded. In the future, groups like this that could be visible to observers on both sides should be recorded as "both"; however it is vital that this be done for ***all*** **groups that could have been seen by observers on both sides and not *only* those that actually were *actually* seen on both sides**. This requires that the single observer who sees a group and knows it could have been seen on the other side but was not, report this to the data recorder.

5. The number and ability of the observers was good and seat positions were rotated correctly, with a limited number (2) of back seat observers. This should be continued on future flights, preferably with the same front seat observer and rear seat observers.

6. I emphasize the importance of continuing to use photography for large horse groups (>10) to ensure that such groups are counted accurately. The current draft of the standard operating procedures for aerial surveys requires use of photography for all groups of >20 horses; however I advise that it be used for groups of >10 horses. There were 32 groups with >10 horses in this survey, only 3 of which were >20 horses. Surveys should continue to use a reliable, high-resolution camera with an adequate telephoto or zoom lens for the distance between observer and horses for this purpose.

Table 2. Tally of raw counts of horses and horse groups by observer (front, back, and both) for combined data from the Frisco HMA, Conger HMA, and Sulphur HMA surveyed in February, 2016.

Observer	Groups Seen (Raw Count)	Horses Seen (Raw Count)	Actual Sighting Rate[a] (groups)	Actual Sighting Rate[a] (horses)
Front	200	1,205	77.2%	81.0%
Back	188	1,138	72.6%	76.5%
Both	129	855	49.8%	57.5%
Combined	259	1,488		

[a] Percentage of all groups seen that were seen by each observer.

Table 3. Effect of observers and sighting condition covariates on estimated sighting probability of horse groups for both front and rear observers. Baseline case (**bold**) for horses presents the predicted sighting probability a group of 4 horses (the median group size observed) that are not moving, in smooth (not rugged) topography, ¼-½ miles from the transect (the most common distance recorded), 0% vegetation and snow cover, and not in high contrast lighting conditions. Other example cases vary a covariate or observer, one effect at a time, as indicated in the left-most column, to illustrate the relative magnitude of each effect. Sighting probabilities for each row should be compared to the baseline (first row) to see the effect of the change in each observer or condition. Baseline values are shown in bold wherever they occur. Sighting probabilities are weighted averages across all 64 models considered (Burnham and Anderson 2002).

	Sighting Probability, Front Observer	Sighting Probability, Back Observer
Baseline	**61.6%**	**71.0%**
Effect of group on centerline	**100%**	0.0%
Effect of group on both sides	100.%	91.6%
Effect of Pilot's Side	59.5%	**71.0%**
Effect of group size (N=1)	61.1%	70.6%
Effect of active group	86.7%	90.9%
Effect of rugged topography	62.7%	72.0%
Effect of vegetation cover (50%)	10.7%	15.4%
Effect of vegetation cover (100%)	0.9%	1.3%
Effect of snow (50%)	56.5%	66.5%
Effect of snow (100%)	61.9%	71.3%
Effect of distance (0-1/4 mile)	86.9%	91.0%
Effect of high contrast lighting	58.3%	68.1%

1.0 Purpose and Need for Action

1.1 Introduction

This environmental assessment (EA) has been prepared to disclose and analyze the environmental impacts of a proposed Population Growth Suppression study that would test the contraceptive effects of an oocyte growth factor vaccine. The Bureau of Land Management (BLM), Nevada State Office (NSO) in cooperation with United States Department of Agriculture, Animal and Plant Health Inspection Services National Wildlife Research Center (NWRC) would conduct the research with previously-gathered wild horses that BLM has removed from the range and determined to be excess. *See* 16 U.S.C. § 1533(b).

This EA analyzes the potential impacts that could result with the implementation of either the Proposed Action or a No-Action alternative to the Proposed Action. BLM also considered other alternatives but has dismissed them from a more detailed analysis as they do not fulfill the purpose and need identified in the EA. Preparation of an EA assists the BLM authorized officer to determine whether to prepare an Environmental Impact Statement (EIS) if significant impacts could result, or a Finding of No Significant Impact (FONSI) if no significant impacts are expected.

1.2 Background

The Wild Free-Roaming Horses and Burros Act (WFRHBA) of 1971 directs BLM to "protect and manage wild free-roaming horses and burros as components of the public lands." 16 U.S.C. § 1333(a). BLM is required to manage the horses and burros in a manner that is "designed to achieve and maintain a thriving natural ecological balance on the public lands." *Id.* The Interior Board of Land Appeals defined the goal for managing wild horse (or burro) populations in a thriving natural ecological balance as follows: "As the court stated in Dahl vs. Clark, supra at 594, the 'benchmark test' for determining the suitable number of wild horses on the public range is 'thriving natural ecological balance.' In the words of the conference committee which adopted this standard: 'The goal of WH&B management should be to maintain a thriving ecological balance (TNEB) between WH&B populations, wildlife, livestock and vegetation, and to protect the range from the deterioration associated with overpopulation of wild horses and burros.'"

The WFRHBA states that BLM must "make determinations as to whether and where an overpopulation exists and whether action should be taken to remove excess animals." *Id.* § 1333(b)(1). To make that determination, BLM has established appropriate management levels (AML) for public lands. *Id.* If the number of wild horses and burros exceeds the AML and action is necessary to remove the animals, BLM must "immediately remove excess animals from the range to achieve" AML. *Id.* § (b)(2). While stating that BLM's management activities should be "at the minimal feasible level," the WFRHBA also mandates that BLM determine whether AML can be achieved "by the removal or destruction of excess animals, or other options (such as sterilization, or natural controls on population levels)." *Id.*; *id.* § 1333(a).

Wild horses and burros tend to have exceptionally high reproductive and survival rates. BLM has determined that the high end of AML for wild horses and burros on the public range across ten western states is 26,690. However, as of March 1, 2019, there was an estimated 88,090 wild horses and burros on the range, 47,468 of which are in the State of Nevada. Therefore, the population on the range exceeds AML by more than 61,400 animals in total – with almost half of those animals in Nevada. In addition to those animals on the range, as of January 17, 2020, there are over 49,500 wild horses and burros that BLM houses in short- and long-term care facilities. BLM gathered and removed these animals from the range after it determined that an overpopulation existed in areas on the range. There is limited funding

and space available for the care of additional animals in short- and long-term care facilities, and insufficient adoption demand for the excess horses removed from the range.

BLM has attempted to address both the high population growth rate of wild horses and burros and the overpopulation on the range by using a variety of methods, including periodic gathers and removals, sex-ratio adjustments, and temporary fertility control vaccines like PZP Zonastat-H, PZP-22 vaccine pellets, and GonaCon. However, these methods have not proven effective at managing the population of wild horses and burros in the long-term or at all herd management areas and herd areas. For example, gathers and removals do not limit the ability of wild horses and burros to reproduce. And, for wild horses there is no currently available fertility control vaccine from which one dose reliably leads to substantial effects that last longer than two years (Rutberg et al. 2017, Baker et al. 2018, Carey et al. 2019). To cause long-lasting physiological effects, existing fertility control vaccines require repeated vaccine applications, which require sufficient budgetary and logistical resources (such as contractors qualified to conduct gathers) and can cause repeated stress to the animals as this generally involves capturing the animals. Capture and vaccination can be difficult for BLM to repeatedly perform at certain herd management areas and herd areas due to the areas' topography, size, skittishness of the horses, etc., on top of budgetary and logistical challenges.

In 2013, the National Research Council of the National Academies of Sciences (NAS) released a report titled "Using science to improve the BLM Wild Horse and Burro Program, a way forward." The NAS Report concluded that it could be useful to have a long-lasting fertility control method available for some situations for wild horse and burro management.

With regards to the duration of a fertility treatment's efficacy, the Report said:

> "Duration of fertility inhibition has major practical importance. Shorter-acting methods require substantially more effort and financial resources to implement even if the cost of the contraceptive itself is low. Longer-acting methods are preferable to minimize requirements for personnel and financial resources and to decrease the frequency of animal handling … In cases in which reversibility is important and repeated treatment is practical, one of the [existing] vaccines would be preferable, with the caution that treatment for more than a few years may prolong recovery of fertility. A single treatment that induces lifetime infertility could be preferable in other situations."

Since 2013, BLM has funded the development and testing of methods that could lead to long-lasting fertility control[1]. BLM's goal is to develop contraceptive treatments that achieve and maintain wild horse population sizes within the established AML, so as to reduce population growth rates in the short term, allow for increased time between gathers, and decrease the number of excess horses that must be removed from the range. The Proposed Action in this EA is designed to determine whether a one-dose oocyte growth factor (OGF) vaccine could be a reliable, long-lasting fertility control method. Oocyte growth factors are proteins that influence the development of oocytes (egg cells) in the ovary. If the one-dose OGF vaccine proves effective, it could be considered for use in future BLM wild horse and burro herd management actions, which management decisions would be subject to additional NEPA compliance.

Decreasing the number of excess wild horses on the range is consistent with findings and recommendations from the National Academy of Sciences (NAS), American Horse Protection Association (AHPA), The American Association of Equine Practitioners (AAEP), Humane Society of the United States (HSUS), Government Accountability Office (GAO), Office of Inspector General (OIG) and

[1] These include, but are not limited to, testing booster doses of GonaCon vaccine, intrauterine devices (IUDs), and new encapsulated formulations of PZP vaccine.

BLM policy; BLM notes that some of those non-governmental groups appear to advocate that removals should take place as part of a broader program that includes fertility control measures. The preface to the NAS report (2013) stated that "It is … evident that the consequences of simply letting horse populations, which increase at a mean annual rate approaching 20 percent, expand to the level of "self-limitation"—bringing suffering and death due to disease, dehydration, and starvation accompanied by degradation of the land—are … unacceptable." The GAO (2008) noted that "Populations that exceed AML can harm the health of the range….The overpopulation of wild horses and burros on the range may negatively impact herd health, rangeland health, and livestock and wildlife that depend on the range."

Contraception Vaccines in Wild Horse Management

As mentioned above, the WFRHBA specifically contemplates BLM using long-lasting fertility control, which could include sterilization, as a population control tool. 16 U.S.C. § 1333(b). No finding of excess animals is required for BLM to pursue contraception in wild horses or wild burros. *Id.*

In recent years, BLM has prioritized expanding the use of fertility control methods to slow population growth rates, reduce the overpopulation of wild horses on public lands, decrease the number of animals that BLM must gather and remove from the range, and protect rangeland ecosystem health. BLM has identified fertility control vaccines as a promising method of contraception. Contraception has been shown to be a cost-effective and humane treatment to slow increases in wild horse populations or, when used with other techniques, to reduce horse population size (Bartholow 2004, de Seve and Boyles-Griffin 2013, Fonner and Bohara 2017). A number of humane contraceptive methods exist, including but not limited to the use of fertility control vaccines (also called immunocontraception), intrauterine devices (IUDs), and humane sterilization techniques; each method has advantages and limitations. Contraception by itself does not remove excess horses from the range. Instead, successful contraception reduces future reproduction. So if a wild horse population is currently above AML, then further action may still be required to remove excess horses in order to achieve a thriving natural ecological balance.

Research to test the efficacy of contraceptive methods in wild horses is valuable to BLM because successful contraception that requires a minimum number of handling occasions would be expected to, among other things,: (1) slow the population growth rate; (2) reduce the frequency of horse gathers; (3) provide alternatives to the current fertility control vaccines which have limited duration of efficacy from one dose; and (4) lower wild horse management costs to taxpayers by reducing the frequency of gathers and lowering the number of horses that BLM must permanently remove and send to short- and long-term care facilities. Bartholow (2007) concluded that the application of 2 or 3-year contraceptives to wild mares could reduce operational costs in a project area by 12-20%, or up to 30% in carefully planned population management programs. Similarly, Hobbs et al. (2000) concluded that population suppression becomes more cost-effective if fertility control is long-lasting. Bartholow (2007) also concluded that contraceptive treatment would likely reduce the number of horses that must be removed in total, with associated reductions in the number of private placements and total holding costs.

Although fertility control treatments on individual wild horses may be associated with some potential physiological, behavioral, demographic, and genetic effects, those impacts are generally minor and transient (other than the temporary or long-lasting loss of reproductive potential for the treated individuals, which is the intended effect), do not prevent overall maintenance of a self-sustaining population, and do not generally outweigh the benefits of using contraceptive treatments in situations where it is a management goal to reduce population growth rates (Garrott and Oli 2013). The use of the oocyte growth factor vaccine for management of wild horses on the range, would be subject to a separate decision-making process and site-specific NEPA compliance, as informed by scientific information available at that time.

Development of a new fertility control vaccine is important as single doses of the existing vaccines are only reliably effective for up to two years. Rutberg et al. 2017, Baker et al. 2018, Carey et al. 2019. Two of the three fertility control treatments that the NAS identified in 2013 as being the "most promising" for immediate use were the porcine zona pellucida (PZP) and gonadotropin releasing hormone (GnRH) fertility control vaccines. Those vaccines were deemed promising partly because of the ease of their delivery method by injection, their availability, their relative efficacy, their lack of effects on scavengers that may eat carcasses of treated animals, and the fact that physiological side effects outside of the reproductive system are limited. Development of a new fertility control vaccine that confers long-lasting effects from a single injected dose would be another, potentially promising, tool for use in wild horse management. The OGF vaccine did not exist when the NAS reviewed fertility control methods available in 2013.

An additional reason that it is prudent to test new types of fertility control vaccines that can be used to manage wild horse populations is the small, but measurable, risk that PZP vaccine availability could be limited in the future, as a result of the growing global incidence of African swine fever. If that disease reaches the United States, then the supply of pig ovaries could be affected, and there may be restrictions on the movements of swine-derived tissues. African swine fever is not known to affect horses. An alternative to PZP would be recombinant zona pellucida (rZP) proteins, which are ZP molecules produced from genetically engineered microbes. Those could be used in vaccines but, as far as BLM is aware, the contraceptive effectiveness of any fertility control vaccines using rZP proteins has not yet been tested on mares in the United States.

Oocyte Growth Factor Vaccine

In 2019, BLM received a proposal from the USDA Animal and Plant Health Inspection Services National Wildlife Research Center (NWRC), for a study designed to test a one-injection formulation of a fertility control vaccine that had preliminary success when used in an earlier formulation that used four injections. If the one-dose formulation of the OGF vaccine is effective, then it could at least cause short-term infertility, and may be able to cause more long-term sterility in treated mares. If the effect lasts more than two or three years, then such a one-dose fertility control vaccine could be critically useful in reducing wild horse growth rates in BLM-administered herd management areas across the west. The research study proposed is responsive to the search for a long-lasting, "…single treatment that induces lifetime infertility…" as was alluded to by the 2013 NAS report.

The proposed study would assess the efficacy and contraceptive effectiveness of the one-dose OGF vaccine, but is not designed to assess behavioral effects of vaccination in free-roaming wild horses (since the study will be conducted on already gathered horses in a more confined environment). The previous four-injection version of the vaccine that would be used in this research has already been tested and appeared safe and successful (Appendix A). The one-treatment vaccine formulation in this research study would induce an immune response to the same oocyte growth factor proteins (called GDF9 and BMP15), but would use a different adjuvant (AdjuVac) and antigen packaging preparation (liposomes) to determine whether a single dose could have the same effect.

Fertility control vaccines meet BLM requirements for safety to mares and the environment (i.e., EPA 2009, 2012, 2013). The oocyte growth factor vaccine would constitute a new form of immunocontraceptive, but would have some of the same advantages that have been identified in other vaccines, including: because they work by causing an immune response in treated animals, there is no risk of hormones or toxins being taken into the food chain when a treated mare dies.

1.3 Purpose and Need for Action

The purpose of the Proposed Action is to test the efficacy of a vaccine against two oocyte growth factors, where the vaccine has been formulated to cause long-lasting contraception from a single dose, on

approximately 16 wild horse mares that have already been permanently removed from the range as excess animals. An equal number of untreated, control mares would live side by side with treated mares. A previously tested version of the vaccine caused contraception for at least 2 years, but it used a weak vaccine adjuvant that required four doses to be effective (results of that study are described in Appendix A).

This action is needed in order to determine whether the one-dose oocyte growth factor vaccine could be a reliable, longer- or long-lasting fertility control method for future BLM wild horse and burro herd management actions, that are subject to separate decisions by BLM and that are covered under separate NEPA documents. Conducting nondestructive research and seeking the recommendations of qualified scientists on matters related to wild horse and burro management is consistent with the provisions of the WFRHBA § 1333(b)(1) and 43 CFR § 46.210 (e).

1.4 Land Use Plan Conformance

The Proposed Action is in conformance with the Carson City Consolidated Resource Management Plan (2001) because it is consistent with national policy listed there to "…preserve and maintain a thriving natural ecological balance…" and with Standard Operating Procedure # 3, "*…contraceptive techniques may be used to slow the rate of an increase of wild horses within the HMAs."*

1.5 Relationship to Laws, Regulations, and Other Plans

Statutes and Regulations

The Proposed Action has been designed to conform with Federal regulations and other authorities that provide official and suggested guidance for management of wild horses by BLM.

1. ***Wild Free-Roaming Horses and Burros Act*** (WFRHBA) of 1971 (Pub. L. 92-195), as amended through the ***Public Rangelands Improvement Act*** of 1978 (Pub. L. 95-514). The Proposed Action is consistent with the WFRHBA specifically, but not limited to, the following:

"§ 1332. Definitions

(f) "excess animals" means wild free-roaming horses or burros (1) which have been removed from an area by the Secretary pursuant to application law…

§ 1333. Powers and duties of the Secretary.

(b) Inventory and determinations; consultation; overpopulations; research study; submittal to Congress.

(1) The Secretary shall … determine whether appropriate management levels should be achieved by the removal or destruction of excess animals, or other options (such as sterilization, or natural controls on population levels). In making such determinations the Secretary shall consult with the United States Fish and Wildlife Service, wildlife agencies of the State or States wherein wild free-roaming horses and burros are located, such individuals independent of Federal and State government as have been recommended by the National Academy of Sciences, and such other individuals whom he determines have scientific expertise and special knowledge of wild horse and burro protection, wildlife management and animal husbandry as related to rangeland management.

(3) For the purpose of furthering knowledge of wild horse and burro population dynamics and their interrelationship with wildlife, forage and water resources, and assisting him in making his determination as to what constitutes excess animals, the Secretary shall contract for a research study of such animals with such individuals independent of Federal and State government as may be recommended by the National Academy of Sciences for having scientific expertise and special knowledge of wild horse and burro protection, wildlife management and animal husbandry as related to rangeland management."

The Proposed Action includes the use of a fertility control vaccine that may cause short-term contraception, long-term-contraception, or sterilization. The wild horses that will take part in the study have been previously determined to be excess animals and were already removed from the wild, as a

result of previous BLM NEPA determinations. The proposed action makes use of USDA APHIS NWRC expertise in animal fertility control methods.

2. ***Federal Land Policy and Management Act*** (Pub. L. 94-579), as amended
The Proposed Action studies a fertility control method that should slow wild horse population growth rates and, therefore, aid BLM in management on the basis of multiple use and sustained yield as described in the FLPMA.

3. ***Wild Free-Roaming Horse and Burro Management*** (43 C.F.R. § 4700)
The Proposed Action is consistent with 43 CFR 4700 specifically, but not limited to, the following:
"4710.4. Constraints on management: Management shall be at the minimum level necessary to attain the objectives identified in approved land use plans and herd management area plans."

The Proposed Action would determine whether a one-dose vaccine could lead to long-term fertility control in wild horses. Currently available fertility control vaccines require more than one dose to have long-lasting effects. Therefore, if the one-dose OGF vaccine is effective in causing long-term infertility, its use could reduce the amount of animal handling that would be required, compared to available vaccines.

4. ***BLM Wild Horses and Burros Management Handbook*** (BLM H-4700-1)
Guidelines in the BLM management Considerations handbook are not legally binding policy, but they do provide suggestions for BLM management. The Proposed Action is consistent with handbook H-4700-1 specifically, but not limited to, the following:
"4.5.3. Reduce Population Growth Rates: "Additional management alternatives (tools) may be considered in the future, pending further research."
"8.1 Other research projects may be initiated as needed to support the management of WH&B."
"8.2 A National Research Advisory Team exists to review research proposals, monitor research project progress, update the Strategy as necessary, and provide recommendations to the WH&B Division Chief…All requests for research and/or research proposals pertaining to the Wild Horse and Burro program, whether generated from the field or through field-related contacts, are to be directed to the Research Advisory Team for review."

The Proposed Action includes the testing of a new fertility control method (one-dose OGF vaccine), which would be responsive to current wild horse management needs, which still include long-lasting fertility control methods that require only one handling occasion. Since the time that handbook H-4700-1 was written, a study at the Northern Nevada Correctional Center (NNCC) revealed that pelleted PZP did not provide adequate long-lasting contraceptive effect. The research proposal from NWRC was reviewed by the BLM WHB Research Advisory Team, which provided a recommendation to the WHB Division Chief.

5. ***BLM Management Considerations*** (BLM H-4710-1)
Guidelines in the BLM management Considerations handbook are not legally binding policy, but they do provide suggestions for BLM management. The Proposed Action is consistent with handbook H-4710-1 specifically, but not limited to, the following:
".5 Research.
.51 Strategic Research Plan. The BLM shall conduct wild horse and burro research in accordance with the priorities identified in the Strategic Research Plan for Wild Horse and Burro Management."

Handbook H-4710-1 refers to the BLM Wild Horse and Burro Strategic Research Plan (BLM 2005), which includes the following guidance: "…the BLM seeks a contraceptive agent that lasts three to five

years following a single injection….Reproduction in wild horses may differ in a number of subtle ways from domestic horses, for example, in the season of estrus cycles. The explanation for these observed differences may be merely environmental, or there may be some minor physiological differences that are inherited. Until the differences can be defined, the BLM has determined that non-invasive research into fertility control could be conducted on captured wild horses held in BLM facilities…" If it is successful, the one-dose OGF vaccine may deliver a form of fertility control that may last three to five years, or longer. The Proposed Action would test the one-dose OGF vaccine in wild horses, in a BLM-contracted facility (the NNCC).

6. ***Comprehensive Animal Welfare Program*** (BLM IM 2015-151)
The Proposed Action is consistent with this policy. Animals in the study will be maintained and cared for in keeping with BLM Comprehensive Animal Welfare Program (Appendix C).

7. ***Animal Health, Maintenance, Evaluation, and Response*** (BLM IM 2015-070)
The Proposed Action is consistent with this policy. Any decision to humanely euthanize animals would be made in conformance with this policy. Euthanasia of otherwise-healthy animals is not a planned part of the Proposed Action.

In addition to the above, the Proposed Action is also consistent with 43 C.F.R. § 46.210, and does not meet any extraordinary circumstance that would require further NEPA review. Despite BLM's conclusion that a Categorical Exclusion could have been an appropriate vehicle for NEPA compliance, BLM Nevada chose to analyze the Action Alternative in an EA to allow for additional public input after publication of a preliminary EA.

1.6 Decision to be Made

The authorized officer would determine whether or not to approve the Proposed Action. The authorized officer's decision is limited to whether to conduct the study. The decision would not set any precedent for use of the vaccine in any future BLM wild horse and burro herd management actions, though preliminary or final results of the proposed study could be taken into consideration in future BLM NEPA determinations.

1.7 Scoping and Identification of Issues

The following issues were identified as a result of internal scoping relative to the BLM's management of wild horses in the planning area:

Impacts to individual wild horses included in the Proposed Action. Measurement indicators for this issue include:

- Expected impacts of handling stress to individual wild horses
- Expected effects of proposed fertility control vaccination
- Potential impacts to animal health and condition
- Potential impacts to pregnant mares and foals
- Potential impacts of vaccination on adoptability

2.0 Description of the Alternatives

2.1 Introduction

This section of the EA describes the Proposed Action and alternatives, including any that were considered but eliminated from detailed analysis. Two alternatives are considered:

- Alternative 1: Proposed Action – Treat approximately 16 mares with oocyte growth factor vaccine and determine efficacy during a three-year study.
- Alternative 2: No Action — Do not conduct the proposed study.

The Proposed Action Alternative was developed to respond to the Purpose and Need. The No Action Alternative would not achieve the identified Purpose and Need. However, it is analyzed in this EA to provide a basis for comparison with the Action Alternative, and to assess the effects of not conducting the proposed study at this time.

2.2 Description of Alternatives Considered in Detail

2.2.1 Management Actions Common to Alternatives 1-2

Whether or not the Proposed Action is taken, the wild horses in the study will be housed and maintained at the Northern Nevada Correctional Center (NNCC) until they are adopted or sold according to existing BLM policy, or are moved to a different off-range facility. BLM contracts with NNCC for the maintenance and care of excess wild horses removed from the range.

2.2.2 Proposed Action

The Proposed Action would include a study designed to test the efficacy of a modified fertility control vaccine in excess wild mares, over a three-year period. This study research is needed to improve the understanding of the effects of a new vaccine that is specific to two ovarian proteins, and which has been designed to be effective after just one dose. The vaccine would be administered as a single injection to the mares in the treatment group.

The one-dose formulation of ovarian growth factor vaccine would include two antigens, BMP15 and GDF9, that have been identified as having a role in oocyte development in the ovary (Galloway et al. 2000, Eckery et al. 2002, Appendix A). These protein antigens would be conjugated to a carrier protein, keyhole limpet hemocyanin (KLH; Curtis et al. 2008), to increase the presentation and longevity of antigen epitopes to the vaccinated mares' immune system. To prolong the immune response further, some or all of the antigen and carrier molecules will be enclosed in spherical, phospholipid bilayer molecules known as liposomes; liposome molecules are a feature of the SpayVac vaccine (Bechert et al. 2013). The adjuvant used to enhance immune response would be one that has been tested and used as a component in other NWRC vaccines, AdjuVac, which contains a small amount of *Mycobacterium avium* as an immunostimulant (Miller et al. 2004). Vaccine success would be measured in terms of the response including at least short-term infertility, with longer-term sterility in treated mares also being a desirable outcome.

Notwithstanding the stated start dates in Appendix A, the timing of the start of the study may depend on administrative factors. The NNCC was selected as a suitable site for the study because it houses and works with excess wild horses removed from the range and has pen designs that are ideal for fertility control studies. The pens are constructed with sturdy materials and high walls, appropriate for housing stallions. These pens have been successfully used in a BLM-funded 2011-2013 pen trial of pelleted versions of a PZP vaccine that also included wild horse mares and stallions in breeding groups that would be similar to the proposed OGF vaccine study design. The same pens at NNCC used for the previous study would be used for the proposed OGF vaccine study.

Research done in coordination with US Department of Agriculture (USDA) Animal Plant Health Inspection Services (APHIS) National Wildlife Research Center (NWRC) would include:

- Treatment of approximately 16 mares with the fertility control vaccine;
- Non-treatment of approximately 16 mares to serve as untreated, 'control' animals;
- Maintenance of mares, in stable groups of 4 treated mares and 4 control mares, with one fertile stallion at a time;

- Periodic blood sampling for hormone and antibody characterization;
- Periodic pregnancy checking via transrectal palpation or ultrasound examination, conducted by a qualified reproductive professional.

Animal care would meet BLM standards identified in the Comprehensive Animal Welfare Program (Appendix C). Holding pens would be approximately 200 feet by 100 feet, with 8 foot tall solid panel fencing. Fertile stallions would be rotated in with mare groups approximately every 3-4 months. To increase the probability that any potentially fertile mares (whether vaccinated or untreated) become pregnant, fertile stallions will be periodically rotated in and out of the bands of stable mares. It is expected that this would happen approximately every 3-4 months. In cases where a mare becomes pregnant, the BLM will take appropriate measures for the safety, welfare, care and handling of pregnant mares and their foals. Approximately 16 mares will receive the one-dose OGF vaccine, and will be monitored throughout the three-year study. The same number of non-pregnant control animals (approximately 16) will be present at the start of each year of the study; to accommodate this need, additional 'control' animals could be added to the study each year as necessary to maintain the sample size of 'control' mares at the start of each year.

The following animal selection stipulations would apply:

- The starting target score for Henneke body condition will be at least 4 for both mares and stallions;
- Mare and stallion ages at the start of the study will be between 3-10 years old;
- Random selection will be used to place mares in either the vaccine-treated group or the untreated control group.

Other Stipulations:

- Guidelines as set forth in the Comprehensive Animal Welfare Program (Welfare Assessment Standards for Gathers) will be followed.
- Individuals handling the vaccine will take standard precautionary steps used when handling any vaccine, to minimize the risk of needle sticks. Out of an abundance of caution, for this study no female humans of childbearing age or younger will be involved with the handling or injection of vaccine.
- During operations, the Lead Contracting Officers Representative (COR) for the BLM contract with the NNCC would be present, or would delegate supervision duties to another BLM employee.
- The BLM contract Veterinarian associated with the NNCC facility, Animal and Plant Health Inspection Service (APHIS) Veterinarian or other licensed Veterinarian would be on call or on site.
- Decisions to humanely euthanize animals would be made in conformance with BLM policy (BLM Washington Office Instruction Memorandum 2015-070).

2.2.3 Alternative 2: No Action

Alternative 2 would be to not test the efficacy of the oocyte growth factor vaccine. This Alternative would not meet the Purpose and Need identified in section 1.3. BLM would not be able to gather information about the long-term efficacy of the oocyte growth factor vaccine that has been formulated for a single injection. Available information about effects of oocyte growth factor vaccines would remain limited to the previous studies that demonstrated the effectiveness of a vaccine administered over four injections, rather than for the single injection formulation.

2.3 Alternatives Considered but Dismissed from Detailed Analysis

2.3.1 PZP Vaccine Study

An alternative in which a PZP vaccine would be tested in a pen trial at NNCC was not considered for detailed analysis. This alternative was not analyzed because BLM has already supported pen trials for two types of PZP vaccine formulations that were intended to cause long-lasting effects from a single dose of vaccine. BLM supported pen trials testing fertility rates of wild mares inoculated with SpayVac vaccine; the mares and fertile stallions were housed at the Pauls Valley, Oklahoma, BLM corral (Roelle et al. 2017). Similarly, nominally long-lasting formulations of PZP vaccine pellets were tested in pen trials at the NNCC from 2011 to 2014, in the same pens that would be used in the Proposed Action, and using similar methods for rotation of fertile stallions with bands of treated and non-treated mares. Results of the most recent trials for both SpayVac (in Oklahoma) and the nominally long-lasting PZP vaccine pellet formulations (at NNCC) did not cause an extended period of infertility, and were discontinued after higher than expected pregnancy rates were observed in treated mares after a short time period (Roelle unpublished results, Turner unpublished results). An additional PZP vaccine trial would not be responsive to the purpose and need identified in this EA, and would not provide BLM with information about a new type of fertility control vaccine that would be free of risk from possible disruptions that could be caused by any future outbreak of African swine fever.

2.3.2 GonaCon Vaccine Study

An alternative in which the GonaCon vaccine would be tested in a pen trial at NNCC was not considered for detailed analysis. An additional GonaCon vaccine trial would not be responsive to the purpose and need identified in this EA. GonaCon is approved for use as a fertility control vaccine in wild horses and burros (EPA 2013). However, this alternative was not analyzed because field trials have already demonstrated that GonaCon is an effective vaccine, with potential for long-lasting efficacy after a second hand-injected dose is administered (Baker et al. 2018). BLM has been supporting an ongoing field trial in Theodore Roosevelt National Park, North Dakota, that aims to determine optimal dose timing and long-term efficacy of GonaCon booster doses. The physiological and contraceptive effects of GonaCon are fairly well understood, and another pen trial with wild horses is not needed for BLM to use this vaccine in wild horse management.

2.3.3 Oocyte Growth Factor Vaccine Study in Domestic Mares

An alternative where the proposed study would take place with domestic horses outside of BLM custody was dismissed from detailed study for several reasons. Most importantly, wild horses are the intended population of use for the vaccine. The vaccine should work in wild horses; it is possible that some phenotypic or physiological traits that are idiosyncratic to wild horses may influence vaccine effectiveness, as noted in the WHB Strategic Research Plan (BLM 2005). Unlike domestic horses, most wild horses have not typically been exposed to numerous vaccines over the course of their lives. There is some possibility that the oocyte growth factor vaccine could interact with the immune system of wild horses in a way that is different from how it interacts with the immune system of domestic horses.

3.0 Affected Environment

This section of the EA briefly discusses the relevant components of the human environment which would be either affected or potentially affected by the Proposed Action or No Action Alternative (refer to Table 2). Direct impacts are those that result from the management actions while indirect impacts are those that exist once the management action has occurred.

3.1 General Description of the Affected Environment

The NNCC is a Nevada state prison facility located on non-federal lands, within Carson City County, Nevada. The topography at NNCC is flat, at an elevation of approximately 4,680 feet. Precipitation in the region of Carson City municipality averages 9.6 inches. Temperatures also vary, from average high

temperatures around 90 degrees Fahrenheit in July to average low temperatures around 22 degrees Fahrenheit in December.

The NNCC grounds include equine facilities suitable for wild horse care, maintenance, and handling by inmates. The facilities include a number of large pens, including eight 100 foot by 200 foot pens that have 8 foot high, smooth steel walls made of highway-grade collision railing. There are runways between all pens that lead to sorting pens. Animals can be humanely moved into runways leading to a padded hydraulic squeeze chute that is suitable for inspections and veterinary care. The nearest public lands are approximately a half mile east of the animal maintenance and handling areas on the NNCC.

There is no public access to the areas of the NNCC where the study would take place, as this area is accessible to inmates and with limited visibility from the security watchtower. Because these are areas with inmate presence, there is no photography, recording or videography allowed in the wild horse maintenance and handling areas of the NNCC. When BLM staff periodically visit the animal maintenance and handling areas of the NNCC, the NNCC requires that any cameras and/or cell phones be left behind and that they be accompanied by a special security escort. Although there are scheduled wild horse and burro adoption events held on NNCC grounds that are open to the public, those events are held in an area where public safety can be ensured. The adoption area has additional security staff are present and are either in uniform or plain clothing, visitors pass through a security check point, the area is apart from where the inmates work, and is separate and distinct from the area where the horses in the study would be housed, cared for by the inmates, vaccinated, and checked for pregnancy.

3.2 Description of Affected Resources/Issues

Table 2 lists the elements of the human environment subject to requirements in statute, regulation, or executive order which must be considered.

Table 2: Supplemental Authorities (Critical Elements of the Human Environment)

Supplemental Authorities	Present	Affected	Rationale
ACECs	**NO**	**NO**	Not present.
Air Quality	**NO**	**NO**	The planning area is within an established prison facility where horses are already housed. The Proposed Action would have no measurable influence on air quality.
Cultural Resources	**NO**	**NO**	Not present.
Environmental Justice	**NO**	**NO**	Not present.
Fish Habitat	**NO**	**NO**	Not present.
Floodplains	**NO**	**NO**	Not present.
Forest and Rangelands	**NO**	**NO**	Not present.
Migratory Birds	**YES**	**NO**	The planning area is within an established prison facility where horses are already housed. Although some migratory birds may occasionally be present on the grounds, the Proposed Action would have no measurable influence on migratory birds.
Native American Religious Concerns	**NO**	**NO**	None known.
Noxious Weeds	**YES**	**NO**	The planning area is within an established prison facility where horses are already housed. The proposed action would have no measurable influence on noxious weeds.
Prime or Unique Farmlands	**NO**	**NO**	Not present.

Riparian-Wetland Zones	**NO**	**NO**	Not present.
T&E Species	**NO**	**NO**	Not present.
Water Quality	**YES**	**NO**	The planning area is within an established prison facility where horses are already housed. The Proposed Action would have no measurable influence on water quality.
Waste (Hazardous or Solid)	**NO**	**NO**	Not present.
Wild and Scenic Rivers	**NO**	**NO**	Not present.
Wilderness and Wilderness Study Area	**NO**	**NO**	Not present.

There are no critical elements of the human environment identified as present and potentially affected by the Proposed Action or by the No Action Alternative. The Proposed Action would take place on the grounds of the Northern Nevada Correctional Center, in an area that does not include any federal lands. In addition to the critical elements listed in Table 2, the only resources that may be affected by the Proposed Action are wild horses that would be included in the proposed action. The affected environment, relative to wild horse resources, is described below.

3.2.1 Wild Horses

Any wild horses included in the Proposed Action would have been previously gathered and removed from the public range as excess animals. They would have arrived at the NNCC as a part of their off-range care. The length of time since the horses were removed from the range may vary by individual animal. Their ages would be between 3-10 years old at the time of the start of the Proposed Action, and their Henneke body condition scores would be at least 4. Any stallion that would be included in the study would still be fertile. To the extent possible, potentially fertile mares would be identified as candidates to be included in the study; this determination could be from BLM records about whether the mare had a foal at her side when she was initially gathered, or if information is available about the mare's current pregnancy status. All animals at the NNCC, whether included in the proposed study or not, are properly fed and watered, consistent with the standards for their maintenance and care.

4.0 Environmental Consequences

4.1 Introduction

This section of the EA documents the potential environmental impacts which would be expected with implementation of the Proposed Action and/or the No Action Alternative. These include the direct impacts (those that result from the management actions) and indirect impacts (those that exist once the management action has occurred).

4.2 Predicted Effects of Alternatives

The direct and indirect impacts to these resources which would be expected to result with implementation of the Proposed Action or No Action Alternative are discussed in detail below.

4.2.1 Wild Horses

Impacts of Proposed Action Alternative

Under the Proposed Action Alternative, impacts to wild horses could be both direct and indirect, occurring to individual horses included in the study. All the wild horses that would be included in the study would have been previously gathered and removed from the public range as excess, and the impacts of gathering, transporting, holding, and adopting horses would have been considered in the NEPA analyses supporting the BLM decisions that led to their gather. The impacts analysis that follows is limited to potential impacts that could result from the Proposed Action; it does not include the impacts of

already-analyzed BLM actions that led the horses being housed at the NNCC, or actions that resulted directly from their prior gathering.

Animal Handling

There is the potential for direct impacts to occur, associated with having wild horses living in a corral setting. Under past management practices, captured mares experienced elevated stress from handling (Ashley and Holcombe 2001), but BLM has instituted guidelines to reduce the sources of handling stress (BLM 2015). The CAWP (Appendix C) would be implemented to ensure that conditions for animal care and welfare are safe and humane, and to minimize potential stress and injury to wild horses. Handling may include freeze-marking, for the purpose of easily identifying individual animals.

It is possible that there could be conflict between individual animals that live together in pens. Such impacts are known to occur intermittently in holding facilities. An example of an indirect individual impact could be a brief 1-2 minute skirmish between animals; usually such conflicts are between studs, and would not be expected in bands with only one stud and eight mares. Injuries typically involve a bite or a kick that bruises, but does not break, the skin. The frequency of this type of minor impact would vary across individual animals. There is the potential for conflict after introduction of new stallions to a group of mares, but the expectation is that the level of that conflict will be low, based on previous experience at the NNCC. The same pens at NNCC that would be used for the proposed study were previously used in a 2011-2013 pen trial of pelleted versions of a PZP vaccine. In that trial, up to 18 mares and one stallion at a time were held per pen, and with stallions rotated to ensure that mares were exposed to fertile stallions. Despite the density of animals in that study being about twice as high as proposed for the OGF vaccine study, no injuries to mares, foals, or stallions were mentioned in progress reports or the final report from that work (Turner, unpublished reports to BLM).

Mares in the Proposed Action that are not treated with the oocyte growth factor vaccine would remain fertile, and would likely become pregnant and produce foals. With 16 untreated mares in the Proposed Action, it is possible that as many as 16 foals could be born per year to these mares, over the course of the 3-year study. Some number of foals may also be born to mares treated with the vaccine.

Foals born to wild mares in the NNCC would have wild horse legal status, and would stay with their mother through the age of weaning (typically 6 months or older). BLM would seek to place these foals into private care through adoption. Researchers may examine or draw blood from foals to determine their reproductive development. It is not expected that either a vaccine-treated or an untreated mare would reject a foal; mares would be living in bands with the same set of other females throughout the study. If a mare dies or must be humanely euthanized during the study, every effort would be made to provide appropriate care to orphaned foals. Veterinarians may administer electrolyte solutions or orphan foals may be fed milk replacer as needed to support their nutritional needs. Orphan foals may be placed in a foster home in order to receive additional care.

In the event of injury or health concerns, any decisions to humanely euthanize animals would be made in conformance with BLM policy. BLM Euthanasia Policy IM-2015-070 is used as a guide to determine if animals meet the criteria and should be euthanized.

Fertility Control Vaccine Direct Effects

All fertility control methods in wild animals are associated with potential risks and benefits, including effects of handling, frequency of handling, physiological effects, behavioral effects, and reduced population growth rates (Hampton et al. 2015). In any vaccine, the antigen molecules are a stimulant to which the body responds with a primary immune response, including the generation of antigen-specific antibodies. Those antibodies can later lead to an immune response that reduces the relative bioavailability of the antigen molecules in the body. Adjuvants are additional substances that are included in vaccines to

elevate the level of immune response. Adjuvants help to strengthen immune responses, and can foster a long-lasting immune response that is specific to the antigen.

Each treated mare would receive a single dose of the oocyte growth factor vaccine. The intended purpose of this vaccine is to cause long-term infertility. Vaccination in this study would be given as a one-time intramuscular injection, by hand. Because the vaccine is designed to impair female fertility, the oocyte growth factor vaccine will not be handled by human females during this study. The vaccine formulation would include GDF9 and BMP 15 proteins conjugated to KLH molecules, encapsulated within liposomes. The vaccine also would include the Adjuvac adjuvant (Miller et al. 2004). Treated mares could experience immune responses to any of those vaccine components. There may be transiently elevated body temperature and injection site soreness.

Most mares recover quickly from the stress of handling, and none is expected to suffer serious long term effects from the injections, other than the direct consequence of temporary or permanent infertility, which is the desired outcome of the vaccination. The oocyte growth factor vaccine should stimulate a persistent immune response resulting in prolonged antibody production against the oocyte growth factors BMP15 and GDF9, the KLH carrier protein, and the adjuvant (Appendix A). Elevated levels of antibodies that are specific against BMP15 and GDF9 should follow vaccination with oocyte growth factor vaccine, which in turn attenuates and disrupts oocyte and / or follicular development (Appendix A). Changes associated with ovarian growth factor vaccination should lead to measurable changes in ovarian structure and function, with the result that ovulation ceases. Specifically, a combined vaccination against both GDF9 and BMP15 appears to cause premature, but incomplete development of follicles in such a way that they do not develop into fully competent ovulatory follicles (Appendix A). Another specific result of vaccination is a lack of observed estrous cycling (Appendix A). There may also be associated changes in hormone concentrations and related physiological effects, consistent with a lack of ovulation and estrus. Preliminary data from a combined oocyte growth factor vaccine against BLM15 and GDF9 indicated that there was a prolonged lack of estrus in mares, even after the level of these antibodies decreased (Appendix A). The effects of the one-dose OGF vaccine, whether temporary or long-lasting, are expected to be comparable to what is observable in mares' seasonal anestrous period, in that during shorter days of fall, winter and early spring, the ovaries are minimally active. Often during that time period small follicles develop but none ovulate. Hormonal changes (gonadal estrogen and progesterone) resulting from OGF vaccination are expected to be consistent with changes that occur naturally both annually, during the shorter days of the non-breeding season, and those that take place in older mares that have reached reproductive senescence (and which, therefore, are no longer cycling). In principle, it is possible that the effects of vaccination may lead to a lifelong dysregulation of oocytes or their growth factors from the ovaries; this would be a form of vaccine-induced sterility.

Treated mares may become only temporarily infertile, or may remain infertile for many years. Of the 10 mares treated with the multi-injection oocyte growth factor vaccine against GDF9 and BMP15 (Appendix A), all 10 were infertile in the first year after vaccination, and 9 of 10 were infertile in the second year (NWRC, unpublished data). Over the course of the proposed 3-year study, it may not be possible to determine whether the one-dose version of the oocyte growth factor vaccine would cause permanent sterility, because mares can live well over 20 years.

If the oocyte growth factor vaccine causes permanent infertility in some or all of treated mares, then that would be consistent with the desired contraceptive effect, and would be similar in outcome to mares treated multiple times with existing PZP vaccines to suppress reproduction, where some horses can become sterile from repeated multiple PZP doses.

Injection site reactions associated with immunocontraceptive treatments are possible in treated mares, as has been seen in mares treated with PZP vaccines (Roelle and Ransom 2009, Joonè et al. 2017) or with

GnRH vaccines (Goodloe 1991, Miller et al. 2008. Roelle and Ransom 2009). The one-dose oocyte growth factor vaccine that would be used in the Proposed Action would include the Adjuvac adjuvant, which is also a component of GonaCon vaccine. As associated with its use in GonaCon, the Adjuvac adjuvant is known to have the potential to cause injection site reactions whether injection is by hand or via darting. Reactions may include some minor degree of inflammation, swelling, and the potential for subcutaneous sterile abscesses, or purulent abscesses, at the injection site (Powers et al. 2011, Baker et al. 2018). Miller et al. (2008) noted that the water and oil emulsion in GonaCon will often cause cysts, granulomas, or sterile subcutaneous abscesses at injection sites; in some cases, a sterile abscess may develop into a draining abscess. In elk treated with GonaCon, Powers et al. (2011) noted up to 35% of treated elk had an abscess, despite the injection sites first being clipped and swabbed with alcohol. Even in studies where swelling and visible abscesses followed GonaCon immunization, the longer term nodules observed did not appear to change any animal's range of movement or locomotor patterns (Powers et al. 2013, Baker et al. 2017, Baker et al. 2018).

It is not expected that the oocyte growth factor vaccine would cause miscarriage in pregnant mares, because the oocyte growth factors that are included in the vaccine are not thought to play a role in fetal development, other than perhaps in ovarian development. A comparison of any observed miscarriage rates in treated and untreated mares could be used to quantify such an effect, if it occurs. Observations following gather operations indicate that the rate of miscarriage varies, but can occur in about 1 to 5% of the captured mares, particularly if the mares are in very thin body condition or in poor health. However, as any mares included in this study would not have been immediately gathered, and their body condition would be at least 4, any miscarriage rate would be expected to be lower. There is some possibility that the fetuses of treated mares would have compromised ovarian function, but this is unlikely because maternal antibodies do not typically cross the placental barrier. Nursing foals may be exposed to oocyte growth factor antibodies in colostrum but antibodies in colostrum do not typically lead to lifelong innate immune responses in nursing offspring.

Infanticide is a rare but natural behavior that has been observed in wild equids (Feh and Munktuya 2008, Gray 2009), but there are no published accounts of infanticide rates increasing as a direct result of fertility control vaccine application in wild horse or burro herds. "Foal stealing," where a near-term pregnant mare steals a neonate foal from a weaker mare, is unlikely to be a common behavioral result of including fertility control vaccine treated mares in a wild horse herd. Any suggestion that there would be a connection between fertility control treatment and "foal stealing" would be speculative, as there has not been any published record of that in a peer-reviewed study. McDonnell (2012) noted that "foal stealing is rarely observed in horses, except under crowded conditions and synchronization of foaling," such as in horse feed lots with extremely high density. Those conditions are not present at NNCC, where pregnant mares will be in large pens with a small number of other animals present, and where the expectation is that any parturition dates would be distributed across the normal foaling season. Killian et al. (2008) conducted a pen trial of several fertility control methods at the NNCC and did not report any signs of infanticide or "foal stealing."

Fertility Control Vaccine Indirect Effects

One expected long-term, indirect effect on wild horses treated with a successful fertility control vaccine would be an improvement in the mares' overall health. This result has been observed in mares treated with PZP vaccine (Turner and Kirkpatrick 2002). Many treated mares would not experience the biological stress of pregnancy, foaling and lactation. An observable measure of improved health is high body condition scores (i.e., Nuñez et al. 2010). If a treated mare returns to fertility, her future foals would be expected to be healthier overall, and would be expected to benefit from improved nutritional quality in the mare's milk. Past application of fertility control vaccines has shown that mares' overall health and body condition remains improved even after fertility resumes. Other types of fertility control vaccine treatment may increase mare survival rates, leading to longer potential lifespan (Turner and Kirkpatrick 2002,

Ransom et al. 2014a). Anecdotal BLM observations of mares treated in past gathers showed that many of the treated mares were larger than, maintained higher body condition than, and had larger healthy foals than untreated mares.

Vaccination with ovarian growth factor vaccine may lead to behavioral effects that are consistent with a lack of estrus. Davis et al. (2018) observed reduced estrus behavior in mares vaccinated with either a GDF9 vaccine or a BMP15 vaccine. However, lack of estrus behaviors does not imply that treated mares will not maintain social relations with other horses. A near lack of estrus behaviors has also been observed in mares vaccinated with a different fertility control vaccine, GonaCon; such a lack of estrus behaviors is very similar to what can be observed in pregnant mares (Ransom et al. 2014b, Baker et al. 2018). In those studies, treated free-roaming mares continued to maintain social relationships with other horses in established social bands. Similarly, free-roaming mares that lacked ovaries appeared to maintain social activity insofar as those mares were always observed with bands of other horses (Collins and Kasbohm 2017).

Mares treated with the oocyte growth factor vaccine may have long-lasting granulomas at the vaccine injection site. This outcome has been observed in mares treated with GonaCon, which is another vaccine with the Adjuvac adjuvant. It is conceivable that mares with granulomas or small visible scars may be more difficult to place into private care in the future. However, the magnitude of any such effect would likely be small, considering that wild horses often have a number of other scars and marks resulting from earlier life events.

The proposed study would not lead to the loss of ovaries in any treated animals. Nonetheless, based on the analogy that removal of ovaries would lead to complete loss of ovarian function, it is possible to make some inferences from literature related to ovariectomy. However, considering that the ovaries would remain in OGF vaccine treated horses, the analogous physiological effects in OGF treated mares would likely be less pronounced than in ovariectomized mares. Even under removal of ovaries – which would not happen in the proposed study – substantial bone density loss would not be expected in wild horses living in conditions such as in the proposed study, or in off-range pastures. The BLM knows of no scientific, peer-reviewed literature that documents bone density loss in mares following ovary loss. A concern has been raised in an opinion article (Nock 2013) that ovary removal in mares could lead to bone density loss. That paper was not peer reviewed nor was it based on research in wild or domestic horses, so it does not meet the BLM's standard for "best available science" on which to base decisions (Kitchell et al. 2015). Hypotheses that are forwarded in Nock (2013) appear to be based on inferences from modern humans leading sedentary lives. Post-menopausal women have a greater chance of osteoporosis (Scholz-Ahrens et al. 1996), though some estrogen is also produced in tissues outside the ovaries. Bone loss in humans has been linked to reduced circulating estrogen. There have been conflicting results when researchers have attempted to test for an effect of reduced estrogen on animal bone loss rates in animal models; all experiments have been on laboratory animals rather than free-ranging wild animals. While some studies found changes in bone cell activity after ovariectomy leading to decreased bone strength (Jerome et al. 1997, Baldock et al. 1998, Huang et al. 2002, Sigrist et al. 2007), others found that changes were moderate and transient or minimal (Scholz-Ahrens et al. 1996, Lundon et al. 1994, Zhang et al. 2007) and even returned to normal after 4 months (Sigrist et al. 2007). Consistent and strenuous use of bones, for instance using jaw bones by eating hard feed, or using leg bones by travelling large distances, appears to limit the negative effects of estrogen deficiency on micro-architecture (Mavropoulos et al. 2014). The effect of exercise on bone strength in animals has been known for many years and has been shown experimentally (Rubin et al. 2001). Dr. Simon Turner, Professor Emeritus of the Small Ruminant Comparative Orthopaedic Laboratory at CSU, conducted extensive bone density studies on ovariectomized sheep, as a model for human osteoporosis. During these studies, he did observe bone density loss on ovariectomized sheep, but those sheep were confined in captive conditions, fed twice a day, had shelter from inclement weather, and had very little distance to travel to get food and water

(Simon Turner, CSU Emeritus, written comm., 2015). Dr. Turner indicated that an estrogen deficiency (i.e., such as might happen if a mare had no ovaries) could potentially affect a horse's bone metabolism, just as it does in sheep and human females when they lead a sedentary lifestyle, but indicated that the constant weight bearing exercise, coupled with high exposure to sunlight ensuring high vitamin D levels, are expected to prevent bone density loss (Simon Turner, CSU Emeritus, written comm., 2015). A horse would have to stay on stall rest for years after removal of the ovaries in order to develop osteoporosis (Simon Turner, CSU Emeritus, written comm. 2015; a stall is a small enclosed space in which an animal cannot move more than a few feet in any given direction). Wild horses that would be involved with the proposed study would neither lose their ovaries, nor be on stall rest.

Two studies raise the concern that treatment with immunocontraceptives could possibly lead to an evolutionary increase in the frequency of individuals whose genetic composition fosters weak immune responses (Cooper and Larson 2006, Ransom et al. 2014a). Many factors influence the strength of a vaccinated individual's immune response, potentially including genetics, but also nutrition, body condition, and prior immune responses to pathogens or other antigens (Powers et al. 2013). The concern is based on an assumption that lack of response to any given fertility control vaccine is a highly heritable trait, and that the frequency of that trait will increase over time in a population with a high fraction of vaccine-treated animals. Cooper and Herbert (2001) reviewed the topic, in the context of concerns about the long-term effectiveness of immunocontraceptives as a control agent for exotic species in Australia. They posit that imunocontraception could be a strong selective pressure, and that selecting for reproduction in individuals with poor immune response could lead to a general decline in immune function in populations where such evolution takes place. Other authors have also speculated that differences in antibody titer responses could be partially due to genetic differences between animals (Curtis et al. 2001, Herbert and Trigg 2005). However, Magiafolou et al. (2013) clarify that if the variation in immune response is due to environmental factors (i.e., body condition, social rank) and not due to genetic factors, then there will be no expected effect of the immune phenotype on future generations. It is possible that general health, as measured by body condition, can have a causal role in determining immune response, with animals in poor condition demonstrating poor immune reactions (NAS 2013). Correlations between physical factors and immune response would not preclude, though, that there could also be some degree of a heritable response to immunocontraception. In studies not directly related to immunocontraception, immune response has been shown to be heritable (Kean et al. 1994, Sarker et al. 1999). Unfortunately, predictions about the long-term, population-level evolutionary response to immunocontraceptive treatments are speculative at this time, with results likely to depend on several factors, including: the strength of the genetic predisposition to not respond to the fertility control vaccine; the heritability of the responsible gene or genes; the initial prevalence of that gene or genes; the number of mares treated with one or more doses of the vaccine; and the actual size of the genetically-interacting metapopulation of horses within which the vaccine treatment takes place. BLM is not aware of any studies that have quantified the heritability of a lack of response to immunocontraception (such as PZP vaccine or GonaCon-Equine) in horses or burros. At this time, there are no studies available from which one could make conclusions about the long-term effects of sustained and widespread immunocontraception treatments on population-wide immune function. Although a few, generally isolated, feral horse populations have been treated with high fractions of mares receiving PZP immunocontraception over long time periods (e.g., Assateague Island National Park, Cape Lookout National Seashore, Pryor Mountains Herd Management Area), no studies have tested for changes in immune competence in those areas. Relative to the large number of free-roaming feral horses in the western United States, immunocontraception has not been, and is not expected to be used in the type of widespread or prolonged manner that might be required to cause a detectable evolutionary response.

In summary, there are few uncertainties about the outcomes of the Proposed Action. The study is designed to determine whether or not individual vaccine-treated mares do, or do not, become infertile and for how long, over the course of the three-year study. There is good reason to quantify those effects and

test the duration of efficacy of the vaccine over three years, but the set of possible outcomes is clearly identified. The initial study conducted with a different formulation of the OGF vaccine required four doses to be effective, but the outcome was infertility, disruption of ovarian follicle development, and a cessation of estrus cycling (Appendix A). Those were the intended consequences, and those are the expected and desired consequences of the one-dose OGF vaccine formulation. The action is not controversial, in the sense that there is no scientifically-based reason to expect general outcomes of vaccination other than either vaccine success or failure (as defined above) in individual treated mares.

Impacts after Study Conclusion
There are potential impacts on wild horses after they are no longer included in the study, or after the study has concluded. If treatment with oocyte growth factor vaccine leads to long-term infertility, it may be of interest to determine whether there are effects on female foals born to treated mares. It is conceivable that a future study could monitor ovarian function in female offspring born to vaccine-treated mares, beyond the 3-year duration of the Proposed Action.

At the end of the study, animals could be placed in private care through adoption or sale with limitations, or could go to long-term care in an off-range pasture (ORP), as already analyzed in the gather decisions that led to their removal from the public range.

Impacts of Alternative 2 (No Action)
Under the No Action Alternative, no elements of the proposed study would affect wild horses at the NNCC. However, wild horses at NNCC would continue to be maintained, housed, fed, and trained at the NNCC, consistent with BLM policy and with the existing BLM-NNCC contract.

4.3 Cumulative Effects

The NEPA regulations define cumulative impacts as impacts on the environment that result from the incremental impact of the Proposed Action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency or person undertakes such actions (40 C.F.R. § 1508.7). Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. The cumulative impacts study area (CSA) for the purposes of evaluating cumulative impacts is limited to the NNCC, and specifically the wild horses that would be included in the Proposed Action.

According to the 1994 BLM *Guidelines for Assessing and Documenting Cumulative Impacts*, the cumulative analysis should be focused on those issues and resource values identified during scoping that are of major importance. Accordingly, the issues of major importance to be analyzed are limited to Wild Horses.

4.3.1 Past and Present Actions

4.3.1.1 Wild Horses

Management actions that have influenced the wild horses at the NNCC are primarily wild horse gathers, which led to the removal of those horses from the range and their designation as excess animals, as a result of previous BLM gather decisions. The Proposed Action Alternative would cause an incremental change in potentially preventing future reproduction for mares treated with the oocyte growth factor vaccine. However, under current management, mares that have been removed from the range and are placed in BLM long-term care facilities do not breed with stallions. Unless they go into private care, wild mares live exclusively with other mares or with gelded (infertile) males. In the context of over 45,000

wild horses living in some form of off-range holding, the loss of reproductive capacity for up to approximately 16 mares treated with the one-dose OGF vaccine would not represent a substantial change.

4.4 Reasonably Foreseeable Future Actions

4.4.1 Wild Horses

It is not expected that genetic health of any wild horse herd in the wild would be impacted by the Proposed Action Alternative, because the animals that would be included in the action would have already been removed from the public lands as excess animals, and would not be expected to be returned to the wild. Any future wild horse management action that could include returning mares from the proposed study back to the wild would be subject to NEPA compliance, following site-specific planning.

Various forms of fertility control can be used in future wild horse and burro herd management. These can help with the goals of maintaining herds at or near AML, reducing fertility rates, and reducing the frequency of gathers and removals. The WFRHBA of 1971 specifically provides for contraception and sterilization (16 U.S.C. 1333 § 3(b)(1)). An extensive body of peer-reviewed scientific literature details the expected impacts of various fertility control methods on wild horses and burros.

The effects of the one-dose oocyte growth factor vaccine may lead to short-term or long-term mare infertility, or to sterility. Regardless, any future BLM herd management actions using the one-dose OGF vaccine in on-range management would also require additional NEPA compliance. The results of the proposed study could help to inform BLM in future decisions about the potential use of the one-dose OGF vaccine. However, a few topics are worth mentioning in the context of reasonably foreseeable future actions.

Additional studies of the short-term and longer-term effects of the single-dose OGF vaccine could be warranted in the future. It is conceivable that the animals in the study could be observed further into the future, either as part of an additional study, or through non-experimental monitoring activities. If that occurs, BLM would ensure that any long-term (i.e., 10-year) study of the same animals is in compliance with NEPA. Although it is possible that the OGF vaccine could be used in a future field trial with wild, free-roaming horses on BLM-managed lands in the future, or as part of management activities, any such future action would be analyzed appropriately with site-specific planning with public involvement, and would not be part of the cumulative effects to the wild horses in the proposed action.

Fertility control that affects individual horses and burros does not prevent BLM from ensuring that there will be self-sustaining populations of wild horses and burros in single herd management areas (HMAs), in complexes of HMAs, and at regional scales of multiple HMAs and complexes. Under the WFRHBA of 1971, BLM is charged with maintaining self-reproducing populations of wild horses and burros. The NAS (2013) encouraged BLM to manage wild horses and burros at the spatial scale of "metapopulations" – that is, across multiple HMAs and complexes in a region. In fact, many HMAs have historical and ongoing genetic and demographic connections with other HMAs, and BLM routinely moves animals from one to another to influence local herd phenotypes and genotypes, and maintain high genetic diversity. Some HMAs could also be managed as non-reproducing, in whole or in part, depending on the specific circumstances and on a case-by-case basis. Thus, although fertility control vaccine-treated individuals may experience long-lasting effects, such as sterility, that does not of itself cause negative demographic or genetic impacts at the level of wild horse populations, which are the object of BLM management for decisions that address wild horse herd management.

Site-specific NEPA analyses for herds that are 'non-reproducing' in whole or in part should be considered in the context of this 'metapopulation' structure, where self-sustaining herds are not necessarily at the

scale of single HMAs. So long as the definition of what constitutes a self-sustaining population includes the larger set of HMAs that have past or ongoing demographic and genetic connections – as is recommended by the NAS 2013 report – it is clear that single HMAs could potentially be managed as nonreproducing in whole or in part while still allowing for a self-sustaining population of wild horses or burros at the broader spatial scale. Wild horses are not an endangered species (USFWS 2015), nor are they rare. Nearly 72,000 adult wild horses and over 16,000 adult wild burros roamed public lands as of March 1, 2019. Those numbers do not include at least 7,500 WH&B on US Forest Service lands, and at least 50,000 feral horses on tribal lands in the Western United States (Wallace et al. 2017, Beever et al. 2018).

Because any future herd management actions that include long-lasting mare contraception, including sterilization, via oocyte growth factor vaccine injection would likely require capturing, handling, and some form of marking, the risks and costs associated with animal capture and handling may be comparable to those of gathering for removal, but would be anticipated to lead to lower subsequent gather, adoption and long-term holding costs and a reduction in excess wild horses that have to be removed from the range. As noted previously, treating mares with a fertility control vaccine may lead to those mares having a longer lifespan. If this were to happen in a herd of horses living on the range, then, changes in lifespan and decreased foaling rates could combine to cause changes in overall age structure in a treated herd (i.e., Turner and Kirkpatrick 2002, Roelle et al. 2010), with a greater prevalence of older mares in the herd (Gross 2000).

If the oocyte growth factor vaccine leads to successful outcomes, in terms of causing long-lasting contraceptive effects, then it is reasonable to expect that BLM might develop guidelines for oocyte growth factor vaccine use in the future, similar to those for other immunocontraceptive vaccines. Existing, non-binding guidelines for fertility vaccine use in BLM wild horse herd management (BLM IM 2009-090) suggest that herds selected for fertility control vaccine use should have background annual growth rates over 5%, have a herd size over 50 animals, and have a target rate of treatment of between 50% and 90% of female wild horses or burros. Guidelines suggest that treated mares should be identifiable via a visible freeze brand or individual color markings, so that their vaccination history is known, and that follow-up population surveys should be used to determine the realized annual growth rate in herds treated with fertility control vaccines.

5.0 Monitoring and Mitigation Measures

The BLM COR assigned to the NNCC contract would be responsible for ensuring contract personnel abide by the contract specifications and the CAWP (Appendix C). Animal care will also be in keeping with protocols approved by the NWRC IACUC (Appendix B). Out of an abundance of caution, the oocyte growth factor vaccine will not be handled by female during this study. Ongoing monitoring of animal health would continue. BLM would continue to contract with an attending veterinarian, to be available for animal care, as needed. NWRC researchers would monitor the immune response and pregnancy status of treated and untreated mares.

6.0 List of Preparers

The following list identifies the interdisciplinary team member's area of responsibility.

Name	Title	Area of Responsibility
Ruth Thompson	Wild Horse Specialist	Project Lead/Wild Horses

Paul Griffin	Research Coordinator	Study Review
David Pritchett	Planning/NEPA/CADR Program Lead	Study Review

7.0 Consultation and Coordination

The NWRC proposal was reviewed by the BLM WHB program research advisory team. The team includes four BLM employees, and one USDA veterinarian not affiliated with NWRC, and has input from the WHB Advisory Board member whose purview is research.

8.0 Public Involvement

A preliminary environmental assessment was made available to interested individuals, agencies, and groups for a 15-day public review and comment period that opened on December 5, 2019 and closed on December 20, 2019 . Forty four comments were received from individuals, organizations, and county or state government agencies. Many of these comments contained overlapping issues/ concerns which were consolidated into 61 distinct topics. Below is a detailed summary of the comments received, BLM's responses, and how BLM used these comments in preparing the final environmental assessment. Comments and Responses can be found in Appendix E.

9.0 Appendices

Appendix A – USDA Research Proposal
Appendix B – USDA Animal Care and Use Protocol
Appendix C – Comprehensive Animal Welfare Program
Appendix D – Literature Cited
Appendix E – Comments and Responses

COMPREHENSIVE ANIMAL WELFARE PROGRAM FOR WILD HORSE AND BURRO GATHERS

IM 2015-151
Instruction Memorandum

UNITED STATES DEPARTMENT OF THE INTERIOR

BUREAU OF LAND MANAGEMENT

WASHINGTON, D.C. 20240-0036

http://www.blm.gov (http://www.blm.gov)

September 25, 2015

In Reply Refer To:

4720 (260) P

EMS TRANSMISSION 09/29/2015

Instruction Memorandum No. 2015-151

Expires: 09/30/2018

To: All Field Office Officials (except Alaska)

From: Assistant Director, Resources and Planning

Subject: Comprehensive Animal Welfare Program for Wild Horse and Burro Gathers

Program Area: Wild Horse and Burro (WH&B) Program

Purpose: The purpose of this Instruction Memorandum (IM) is to establish policy for the Wild Horse and Burro (WH&B) Gather component of the Comprehensive Animal Welfare Program (CAWP). It defines standards, training and monitoring for conducting safe, efficient and successful WH&B gather operations

while ensuring humane care and handling of animals gathered.

Policy/Action: The Bureau of Land Management (BLM) is committed to the well-being and responsible care of WH&B we manage. At all times, the care and treatment provided by the BLM and its contractors will be characterized by *compassion and concern* for WH&B well-being and welfare needs.

All State, District and Field Offices are required to comply with the CAWP policy for all gathers within their jurisdiction. The CAWP for WH&B gathers includes three components:

1. Comprehensive Animal Welfare Program Standards for Wild Horse and Burro Gathers (Attachment 1): These standards include requirements for trap and temporary holding facility design; capture and handling; transportation; and appropriate care after capture. The standards have been incorporated into helicopter gather contracts as specifications for performance.
2. Training: All Incident Commanders (IC), Contracting Officer Representatives (COR), Project Inspectors (PI) and contractors must complete a mandatory training course. The training is available online via DOI Learn: Course Title: BLM's Comprehensive Animal Welfare Program (CAWP) – gathers; Course Number: 4700-13.
3. CAWP Gather Assessment Tool (Attachment 2): The Gather Assessment Tool will be used during FY2016 for evaluating the effectiveness of mandatory training and adequacy of the Standards for CAWP for WH&B Gathers. The WO-260 Division is responsible for overseeing implementation of assessments as well as providing the necessary access to the assessment tool for those gathers selected for internal assessment during FY2016.
4. Starting in FY2017, the Assessment Tool will be used to evaluate compliance by the BLM and its contractors with the Standards for CAWP for WH&B Gathers. The WO-260 Division will oversee the completion of all assessments as well as providing the necessary access to the assessment tool for those gathers identified for both internal and external assessment by internal and external personnel during FY2017.

This IM supersedes Interim IM No. 2013-059, Wild Horse and Burro Gathers: Comprehensive Animal Welfare Policy which was issued as part of a package of IMs covering various aspects of the management of WH&B gathers, including:

- IM No. 2013-058, Wild Horse and Burro Gathers: Public and Media Management.
- IM No. 2013-060, Wild Horse and Burro Gathers: Management by Incident Command System
- IM No. 2013-061, Wild Horse and Burro Gathers: Internal and External Communicating and Reporting

The goal of this IM is to ensure that the responsibility for humane care and treatment of WH&Bs remains a high priority for the BLM and its contractors at all times. The Bureau's objective is to use the best available science, husbandry and handling practices applicable for WH&Bs and to make improvements whenever possible, while also meeting our overall gather goals and objectives in accordance with current BLM policy, standard operating procedures and contract requirements. The CAWP and its associated components will be reviewed regularly and modified as necessary to enhance its transparency and effectiveness in assuring the humane care and treatment of the WH&Bs.

The Lead COR is the primary party responsible for promptly addressing any actions that are inconsistent with the Standards set forth in the CAWP. The Lead COR may delegate responsibility to an alternate COR. The Lead COR will promptly notify the contractor if any improper or unsafe actions are observed and will ensure that they are promptly rectified. If issues are left unresolved or immediate action is required, the Lead COR has the authority to suspend gather operations. Through coordination with the Contracting Officer, the Lead COR shall, if necessary, ensure that corrective measures have been taken to prevent such actions from reoccurring and all follow-up and corrective measures shall be reported as a component of the Lead COR's daily reports.

Timeframe: All portions of this policy are effective as of October 1st, 2015.

Budget Impact: This IM is implementing new policy and guidance with additional training and reporting requirements for personnel and contractors. The cost for the required training is about $250 per person. CAWP program implementation, oversight, data compilation and reporting requirements will require an additional 12 to 15 work months per year.

Background: The authority for a Comprehensive Animal Welfare Program for WH&B Gathers is provided by Public Law 92-195, Wild Free-Roaming Horses and Burros Act of 1971 (as amended) and 43 CFR 4700.0-2.

The Comprehensive Animal Welfare Program for WH&B gathers consolidates and highlights the BLM's policies, procedures and ongoing commitment to protect animal welfare; provide training for employees and contractors on animal care and handling; and implement a gather assessment tool which will be used to evaluate the agency's and contractor's adherence to standards for the handling and care of animals during gather operations.

Manual/Handbook Sections Affected: None

Coordination: This IM was coordinated among WO-100, WO-200, WO-260, WO-600, WH&B State Leads and WH&B Specialists.

Contact: Bryan Fuell, On-Range Branch Chief, Wild Horse and Burro Program, at 775-861-6611.

WILD HORSE AND BURRO COMPREHENSIVE ANIMAL WELFARE PROGRAM

PIM 2021-002
Permanent Instruction Memorandum

December 18, 2020

In Reply Refer To:
4700 (260) P

EMS TRANSMISSION 12/18/2020
Permanent Instruction Memorandum No. 2020- 002

To: All Headquarters Officials and Field Office Officials

Attn: State and Center Directors

From: Assistant Director, Resources and Planning

Subject: Wild Horse and Burro Comprehensive Animal Welfare Program

Program Area: Wild Horse and Burro Program

Purpose: The purpose of this Permanent Instruction Memorandum (PIM) is to re-affirm the Bureau of Land Management's (BLM's) longstanding commitment to ensure the humane treatment of wild horses and burros (WHB) in all on-range and off-range management activities through the Comprehensive Animal Welfare Program (CAWP). The humane treatment of wild horses and burros outlined in this policy reiterates the BLM's longstanding practices but also provides additional clarification to BLM employees. This PIM consolidates current humane practices, incorporates the existing Standard Operating Procedures (SOPs) outlined in Attachments 1 and 2 to ensure humane care and handling of the animals, and increases transparency concerning the humane treatment of wild horses and burros.

Policy/Action: The BLM is committed to continue protecting animal welfare and providing humane care and treatment to WHBs both on and off the range. Consistent with long-standing policies and practices, the handling and treatment provided by the BLM, its contractors, and its partners is based on compassion and concern for the animals' well-being at all times. Animals are managed and cared for to optimize animal condition, health, and safety.

All state, district, and field offices will continue to comply with the WHB CAWP policy within their jurisdiction at all times. The WHB CAWP policy includes:

1. CAWP Standards for Wild Horse and Burro Gathers (Attachment 1): These standards include requirements for trap and temporary holding facility design, capture and handling, transportation, and care after capture. The standards are also incorporated into helicopter gather contracts as specifications for performance.
2. Training for gather operations: All BLM staff associated with gather operations (incident commanders, contracting officer representatives, project inspectors, public affairs officials, and law enforcement officers) and contractor crews are required to complete online training annually for CAWP – Gathers (BLM-TC-4700-13), which is available through DOI Talent.
3. CAWP Standards for Off-Range Corral Facilities, Transportation, and Adoption/Sale Events (Attachment 2): This includes requirements for holding of animals in off-range corrals, transportation, and adoptions/sales events. These SOPs are incorporated into off-range corral contracts as specifications for performance.
4. Training for the Care, Handling, and Transportation of Wild Horses and Burros at off-range corrals and adoption/sales events: All personnel, including contractors and partners involved in the care, handling, and transportation of wild horses and burros at off-range

CAWP STANDARDS OFF RANGE CORRAL TRANSPORT ADOPTION SALE EVENTS (PDF / 364 KB)

FISCAL YEAR

2021

corrals and adoption/sale events are required to complete online training annually. Development of this training will begin following issuance of this PIM.

5. CAWP Standards and SOPs (to be developed) for animals on the range, in off-range pastures, and public off-range pastures: All personnel, contractors, and partners involved in management of WHBs on the range, in off-range pastures, or public off-range pastures are required to complete online training annually following the development of these guidelines and SOPs.

The purpose of this PIM is to continue to ensure that the humane care and treatment of WHBs remains the priority for the BLM, its contractors, and its partners. The BLM will continue to use the best available science, husbandry, and handling practices applicable for WHBs. Whenever possible, the BLM will make improvements to its practices while also meeting planned objectives in accordance with current BLM policy, SOPs, as well as contractual and cooperative agreement requirements. The CAWP will be reviewed periodically by WHB program leadership and modified as necessary to strengthen public trust, transparency, and effectiveness in assuring the humane care and treatment of the WHBs.

The authorized officer is the primary party responsible for immediately addressing any actions that are inconsistent with the CAWP. Consistent with applicable BLM delegation of authority manuals, the authorized officer may delegate responsibility to an alternate individual. The authorized officer should promptly notify the employees, contractors, and partners of actions that are not compliant with the CAWP and correct all issues immediately. It is the responsibility of all individuals engaged in actions throughout the WHB program to implement all aspects of the CAWP.

The WHB CAWP Coordinator will lead the implementation, development, and modification of all aspects of the CAWP, including those developed to date as well as future components of the CAWP.

Timeframe: This policy is effective immediately.

Budget Impact: This PIM codifies long-standing policy, practice, and guidance to include mandatory annual training and reporting requirements for BLM personnel, contractors, and partners associated with gather operations. The cost for the required training is approximately $100 per person per year. This PIM also formalizes SOPs for off-range holding, adoptions, sales, and transportation of excess WHB. When fully developed, the CAWP program implementation, oversight, data compilation, and reporting requirements will require an additional 12 to 18 work months per year.

Background: Public Law-195, Wild Free-Roaming Horses and Burros Act of 1971 (as amended) and 43 CFR 4700.0-2 provide the authority for a CAWP for WHB.

This CAWP policy provides a comprehensive approach to long-standing policies and practices within the BLM WHB program. Despite these policies and practices, the BLM has been criticized by some animal protection organizations on its handling and care of wild horses and burros, especially during the gathering activities and transitioning of the horses from public lands to off-range facilities. Some of the criticisms include concerns as to the transportation conditions of the horses, facility design, environmental conditions, handling practices, and nutrition. Similar to policies adopted by other organizations in agricultural and animal research industries, this PIM establishes a framework to ensure there are programs in place to verify humane care and handling of animals. It provides transparency on how the animals are assured humane care and proper handling. This framework seeks to confirm that the WHB program is conducted in a humane and caring manner.

The CAWP for WHB consolidates and highlights the BLM policies, procedures, and ongoing commitment to protect animal welfare; provides training for employees, contractors, and partners on animal care and handling, and implements assessment tools to evaluate adherence to the CAWP SOP by the agency, contractors, and partners.

Manual/Handbook Sections Affected: This PIM affects policies in BLM Manual/Handbooks H-4700-1 “Wild Horse and Burro Management” and H-4750-2 “Adoption of Wild Horses and Burros”.

Coordination: This PIM was coordinated among HQ-100, HQ-200, HQ-260, HQ-600, Deputy State Directors, WHB State Leads, APHIS Veterinarian, WHB Facility Managers, and WHB Specialists.

Contact: If you have any questions, please contact the Wild Horse and Burro Division Chief, at 866-468-7826 or wildhorse@blm.gov.

STANDARDS

Standard Definitions

Major Standard: Impacts the health or welfare of WH&Bs. Relates to an alterable equipment or facility standard or procedure. Appropriate wording is "must," "unacceptable," "prohibited."

Minor Standard: unlikely to affect WH&Bs health or welfare or involves an uncontrollable situation. Appropriate wording is "should."

Lead COR = Lead Contracting Officer's Representative

COR = Contracting Officer's Representative

PI = Project Inspector

WH&Bs = Wild horses and burros

I. FACILITY DESIGN

A. Trap Site and Temporary Holding Facility

1. The trap site and temporary holding facility must be constructed of stout materials and must be maintained in proper working condition, including gates that swing freely and latch or tie easily. (**major**)
2. The trap site should be moved close to WH&B locations whenever possible to minimize the distance the animals need to travel.(minor)
3. If jute is hung on the fence posts of an existing wire fence in the trap wing, the wire should be either be rolled up or let down for the entire length of the jute in such a way that minimizes the possibility of entanglement by WH&Bs unless otherwise approved by the Lead COR/COR/PI. (minor)
4. Fence panels in pens and alleys must be not less than 6 feet high for horses, 5 feet high for burros, and the bottom rail must not be more than 12 inches from ground level. (**major**)

5. The temporary holding facility must have a sufficient number of pens available to sort WH&Bs according to gender, age, number, temperament, or physical condition. (**major**)
    a. All pens must be assembled with capability for expansion. (**major**)
    b. Alternate pens must be made available for the following: (**major**)
        1) WH&Bs that are weak or debilitated
        2) Mares/jennies with dependent foals
    c. WH&Bs in pens at the temporary holding facility should be maintained at a proper stocking density such that when at rest all WH&Bs occupy no more than half the pen area. (minor)
6. An appropriate chute designed for restraining WH&Bs must be available for necessary procedures at the temporary holding facility. This does not apply to bait trapping operations unless directed by the Lead COR/COR/PI. (**major**)
7. There must be no holes, gaps or openings, protruding surfaces, or sharp edges present in fence panels or other structures that may cause escape or possible injury. (**major**)
8. Padding must be installed on the overhead bars of all gates and chutes used in single file alleys. (**major**)
9. Hinged, self-latching gates must be used in all pens and alleys except for entry gates into the trap, which may be secured with tie ropes. (**major**)
10. Finger gates (one-way funnel gates) used in bait trapping must be constructed of materials approved by the Lead COR/COR/PI. Finger gates must not be constructed of materials that have sharp ends that may cause injuries to WH&Bs, such as "T" posts, sharpened willows, etc. (**major**)
11. Water must be provided at a minimum rate of ten gallons per 1000 pound animal per day, adjusted accordingly for larger or smaller horses, burros and foals, and environmental conditions, with each trough placed in a separate location of the pen (i.e. troughs at opposite ends of the pen). Water must be refilled at least every morning and evening. (**major**)
12. The design of pens at the trap site and temporary holding facility should be constructed with rounded corners. (minor)

13. All gates and panels in the animal holding and handling pens and alleys of the trap site must be covered with materials such as plywood, snow fence, tarps, burlap, etc. approximately 48" in height to provide a visual barrier for the animals. All materials must be secured in place.(**major**)

    These guidelines apply:

    a. For exterior fences, material covering panels and gates must extend from the top of the panel or gate toward the ground.(**major**)
    b. For alleys and small internal handling pens, material covering panels and gates should extend from no more than 12 inches below the top of the panel or gate toward the ground to facilitate visibility of animals and the use of flags and paddles during sorting. (minor)
    c. The initial capture pen may be left uncovered as necessary to encourage animals to enter the first pen of the trap. (minor)

14. Non-essential personnel and equipment must be located to minimize disturbance of WH&Bs. (**major**)
15. Trash, debris, and reflective or noisy objects should be eliminated from the trap site and temporary holding facility. (minor)

B. Loading and Unloading Areas

1. Facilities in areas for loading and unloading WH&Bs at the trap site or temporary holding facility must be maintained in a safe and proper working condition, including gates that swing freely and latch or tie easily. (**major**)
2. The side panels of the loading chute must be a minimum of 6 feet high and fully covered with materials such as plywood or metal without holes that may cause injury. (**major**)
3. There must be no holes, gaps or openings, protruding surfaces, or sharp edges present in fence panels or other structures that may cause escape or possible injury. (**major**)
4. All gates and doors must open and close easily and latch securely. (**major**)

5. Loading and unloading ramps must have a non-slip surface and be maintained in a safe and proper working condition to prevent slips and falls. Examples of non-slip flooring would include, but not be limited to, rubber mats, sand, shavings, and steel reinforcement rods built into ramp. There must be no holes in the flooring or items that can cause an animal to trip. (**major**)
6. Trailers must be properly aligned with loading and unloading chutes and panels such that no gaps exist between the chute/panel and floor or sides of the trailer creating a situation where a WH&B could injure itself. (**major**)
7. Stock trailers should be positioned for loading or unloading such that there is no more than 12" clearance between the ground and floor of the trailer for burros and 18" for horses. (minor)

II. CAPTURE TECHNIQUE

A. Capture Techniques

1. WH&Bs gathered on a routine basis for removal or return to range must be captured by the following approved procedures under direction of the Lead COR/COR/PI. (**major**)
   a. Helicopter
   b. Bait trapping
2. WH&Bs must not be captured by snares or net gunning. (**major**)
3. Chemical immobilization must only be used for capture under exceptional circumstances and under the direct supervision of an on-site veterinarian experienced with the technique. (**major**)

B. Helicopter Drive Trapping

1. The helicopter must be operated using pressure and release methods to herd the animals in a desired direction and should not repeatedly evoke erratic behavior in the WH&Bs causing injury or exhaustion. Animals must not be pursued to a point of exhaustion; the on-site veterinarian must examine WH&Bs for signs of exhaustion. (**major**)

2. The rate of movement and distance the animals travel must not exceed limitations set by the Lead COR/COR/PI who will consider terrain, physical barriers, access limitations, weather, condition of the animals, urgency of the operation (animals facing drought, starvation, fire, etc.) and other factors. (**major**)
    a. WH&Bs that are weak or debilitated must be identified by BLM staff or the contractors. Appropriate gather and handling methods should be used according to the direction of the Lead COR/COR/PI. (**major**)
    b. The appropriate herding distance and rate of movement must be determined on a case-by-case basis considering the weakest or smallest animal in the group (e.g., foals, pregnant mares, or horses that are weakened by body condition, age, or poor health) and the range and environmental conditions present. (**major**)
    c. Rate of movement and distance travelled must not result in exhaustion at the trap site, with the exception of animals requiring capture that have an existing severely compromised condition prior to gather. Where compromised animals cannot be left on the range or where doing so would only serve to prolong their suffering, euthanasia will be performed in accordance with BLM policy. (**major**)
3. WH&Bs must not be pursued repeatedly by the helicopter such that the rate of movement and distance travelled exceeds the limitation set by the Lead COR/COR/PI. Abandoning the pursuit or alternative capture methods may be considered by the Lead COR/COR/PI in these cases. (**major**)
4. When WH&Bs are herded through a fence line en route to the trap, the Lead COR/COR/PI must be notified by the contractor. The Lead COR/COR/PI must determine the appropriate width of the opening that the fence is let down to allow for safe passage through the opening. The Lead COR/COR/PI must decide if existing fence lines require marking to increase visibility to WH&Bs. (**major**)
5. The helicopter must not come into physical contact with any WH&B. The physical contact of any WH&B by helicopter must be documented by Lead COR/COR/PI along with the circumstances. (**major**)
6. WH&Bs may escape or evade the gather site while being moved by the helicopter. If there are mare/dependent foal pairs in a group being brought to a trap and half of an identified pair is thought to have evaded capture, multiple attempts by helicopter may

be used to bring the missing half of the pair to the trap or to facilitate capture by roping. In these instances, animal condition and fatigue must be evaluated by the Lead COR/COR/PI or on-site veterinarian on a case-by-case basis to determine the number of attempts that can be made to capture an animal.(**major**)

7. Horse captures must not be conducted when ambient temperature at the trap site is below 10ºF or above 95ºF without approval of the Lead COR/COR/PI. Burro captures must not be conducted when ambient temperature is below 10ºF or above 100ºF without approval of the Lead COR/COR/PI. The Lead COR/COR/PI will not approve captures when the ambient temperature exceeds 105 ºF. (**major**)

C. Roping

1. The roping of any WH&B must be approved prior to the procedure by the Lead COR/COR/PI. (**major**).
2. The roping of any WH&B must be documented by the Lead COR/COR/PI along with the circumstances. WH&Bs may be roped under circumstances which include but are not limited to the following: reunite a mare or jenny and her dependent foal; capture nuisance, injured or sick WH&Bs or those that require euthanasia; environmental reasons such as deep snow or traps that cannot be set up due to location or environmentally sensitive designation; and public and animal safety or legal mandates for removal. (**major**)
3. Ropers should dally the rope to their saddle horn such that animals can be brought to a stop as slowly as possible and must not tie the rope hard and fast to the saddle so as to intentionally jerk animals off their feet. (**major**)
4. WH&Bs that are roped and tied down in recumbency must be continuously observed and monitored by an attendant at a maximum of 100 feet from the animal. (**major**)
5. WH&Bs that are roped and tied down in recumbency must be untied within 30 minutes. (**major**)
6. If the animal is tied down within the wings of the trap, helicopter drive trapping within the wings will cease until the tied-down animal is removed. (**major**)
7. Sleds, slide boards, or slip sheets must be placed underneath the animal's body to move and/or load recumbent WH&Bs. (**major**)

8. Halters and ropes tied to a WH&B may be used to roll, turn, position or load a recumbent animal, but a WH&B must not be dragged across the ground by a halter or rope attached to its body while in a recumbent position. (**major**)
9. Animals captured by roping must be evaluated by the on-site/on-call veterinarian within four hours after capture, marked for identification at the trap site, and be re-evaluated periodically as deemed necessary by the on-site/on-call veterinarian. (**major**)

D. Bait Trapping

1. WH&Bs may be lured into a temporary trap using bait (feed, mineral supplement, water) or sexual attractants (mares/jennies in heat) with the following requirements:
   a. The period of time water sources other than in the trap site are inaccessible must not adversely affect the wellbeing of WH&Bs, wildlife or livestock, as determined by the Lead COR/COR/PI. (**major**)
   b. Unattended traps must not be left unobserved for more than 12 hours. (**major**)
   c. Mares/jennies and their dependent foals must not be separated unless for safe transport. (**major**)
   d. WH&Bs held for more than 12 hours must be provided with accessible clean water at a minimum rate of ten gallons per 1000 pound animal per day, adjusted accordingly for larger or smaller horses, burros and foals and environmental conditions. (**major**)
   e. WH&Bs held for more than 12 hours must be provided good quality hay at a minimum rate of 20 pounds per 1000 pound adult animal per day, adjusted accordingly for larger or smaller horses, burros and foals. (**major**)
      1) Hay must not contain poisonous weeds, debris, or toxic substances. (**major**)
      2) Hay placement must allow all WH&Bs to eat simultaneously. (**major**)

III. WILD HORSE AND BURRO CARE

A. Veterinarian

1. On-site veterinary support must be provided for all helicopter gathers and on-site or on-call support must be provided for bait trapping. (**major**)

2. Veterinary support must be under the direction of the Lead COR/COR/PI. The on-site/on-call veterinarian will provide consultation on matters related to WH&B health, handling, welfare, and euthanasia at the request of the Lead COR/COR/PI. All decisions regarding medical treatment or euthanasia will be made by the on-site Lead COR/COR/PI. (**major**)

B. Care

1. Feeding and Watering
    a. Adult WH&Bs held in traps or temporary holding pens for longer than 12 hours must be fed every morning and evening with water available at all times other than when animals are being sorted or worked. (**major)**
    b. Water must be provided at a minimum rate of ten gallons per 1000 pound animal per day, adjusted accordingly for larger or smaller horses, burros and foals, and environmental conditions, with each trough placed in a separate location of the pen (i.e. troughs at opposite ends of the pen). . (**major**)
    c. Good quality hay must be fed at a minimum rate of 20 pounds per 1000 pound adult animal per day, adjusted accordingly for larger or smaller horses, burros and foals. (**major**)
        i. Hay must not contain poisonous weeds or toxic substances. (**majo**r)
        ii. Hay placement must allow all WH&Bs to eat simultaneously. (**major**)
    d. When water or feed deprivation conditions exist on the range prior to the gather, the Lead COR/COR/PI should adjust the watering and feeding arrangements in consultation with the onsite veterinarian as necessary to provide for the needs of the animals. (minor)
2. Dust abatement
    a. Dust abatement by spraying the ground with water must be employed when necessary at the trap site and temporary holding facility. (**major**)

3. Trap Site
    a. Dependent foals or weak/debilitated animals must be separated from other WH&Bs at the trap site to avoid injuries during transportation to the temporary holding facility. Separation of dependent foals from mares must not exceed four hours unless the Lead COR/COR/PI authorizes a longer time or a decision is made to wean the foals. (**major**)
4. Temporary Holding Facility
    a. All WH&Bs in confinement must be observed at least once daily to identify sick or injured WH&Bs and ensure adequate food and water. (**major**)
    b. Foals must be reunited with their mares/jennies at the temporary holding facility within four hours of capture unless the Lead COR/COR/PI authorizes a longer time or foals are old enough to be weaned during the gather. (**major**)
    c. Non-ambulatory WH&Bs must be located in a pen separate from the general population and must be examined by the BLM horse specialist and/or on-call or on-site veterinarian as soon as possible, no more than four hours after recumbency is observed. Unless otherwise directed by a veterinarian, hay and water must be accessible to an animal within six hours after recumbency.(**major**)
    d. Alternate pens must be made available for the following: (**major**)
        1) WH&Bs that are weak or debilitated
        2) Mares/jennies with dependent foals
    e. Aggressive WH&Bs causing serious injury to other animals should be identified and relocated into alternate pens when possible. (minor)
    f. WH&Bs in pens at the temporary holding facility should be maintained at a proper stocking density such that when at rest all WH&Bs occupy no more than half the pen area. (minor)

C. Biosecurity

1. Health records for all saddle and pilot horses used on WH&B gathers must be provided to the Lead COR/COR/PI prior to joining a gather, including: (**major**)
   a. Certificate of Veterinary Inspection (Health Certificate, within 30 days).
   b. Proof of:
      1) A negative test for equine infectious anemia (Coggins or EIA ELISA test) within 12 months.
      2) Vaccination for tetanus, eastern and western equine encephalomyelitis, West Nile virus, equine herpes virus, influenza, *Streptococcus equi*, and rabies within 12 months.
2. Saddle horses, pilot horses and mares used for bait trapping lures must not be removed from the gather operation (such as for an equestrian event) and allowed to return unless they have been observed to be free from signs of infectious disease for a period of at least three weeks and a new Certificate of Veterinary Examination is obtained after three weeks and prior to returning to the gather. (**major**)
3. WH&Bs, saddle horses, and pilot horses showing signs of infectious disease must be examined by the on-site/on-call veterinarian. (**major**)
   a. Any saddle or pilot horses showing signs of infectious disease (fever, nasal discharge, or illness) must be removed from service and isolated from other animals on the gather until such time as the horse is free from signs of infectious disease and approved by the on-site/on-call veterinarian to return to the gather. (**major**)
   b. Groups of WH&Bs showing signs of infectious disease should not be mixed with groups of healthy WH&Bs at the temporary holding facility, or during transport. (minor)
4. Horses not involved with gather operations should remain at least 300 yards from WH&Bs, saddle horses, and pilot horses being actively used on a gather. (minor)

IV. HANDLING

A. Willful Acts of Abuse

1. Hitting, kicking, striking, or beating any WH&B in an abusive manner is prohibited. (**major**)
2. Dragging a recumbent WH&B without a sled, slide board or slip sheet is prohibited. Ropes used for moving the recumbent animal must be attached to the sled, slide board or slip sheet unless being loaded as specified in Section II. C. 8. (**major**)
3. There should be no deliberate driving of WH&Bs into other animals, closed gates, panels, or other equipment. (minor)
4. There should be no deliberate slamming of gates and doors on WH&Bs. (minor)
5. There should be no excessive noise (e.g., constant yelling) or sudden activity causing WH&Bs to become unnecessarily flighty, disturbed or agitated. (minor)

B. General Handling

1. All sorting, loading or unloading of WH&Bs during gathers must be performed during daylight hours except when unforeseen circumstances develop and the Lead COR/CO/PI approves the use of supplemental light. (**major**)
2. WH&Bs should be handled to enter runways or chutes in a forward direction. (minor)
3. WH&Bs should not remain in single-file alleyways, runways, or chutes longer than 30 minutes. (minor)
4. Equipment except for helicopters should be operated and located in a manner to minimize flighty behavior . (minor)

C. Handling Aids

1. Handling aids such as flags and shaker paddles must be the primary tools for driving and moving WH&Bs during handling and transport procedures. Contact of the flag or paddle end of primary handling aids with a WH&B is allowed. Ropes looped around the hindquarters may be used from horseback or on foot to assist in moving an animal forward or during loading. (**major**)

2. Electric prods must not be used routinely as a driving aid or handling tool. Electric prods may be used in limited circumstances only if the following guidelines are followed:
    a. Electric prods must only be a commercially available make and model that uses DC battery power and batteries should be fully charged at all times. (**major**)
    b. The electric prod device must never be disguised or concealed. (**major**)
    c. Electric prods must only be used after three attempts using other handling aids (flag, shaker paddle, voice or body position) have been tried unsuccessfully to move the WH&Bs. (**major**)
    d. Electric prods must only be picked up when intended to deliver a stimulus; these devices must not be constantly carried by the handlers. (**major**)
    e. Space in front of an animal must be available to move the WH&B forward prior to application of the electric prod. (**major**)
    f. Electric prods must never be applied to the face, genitals, anus, or underside of the tail of a WH&B. (**major**)
    g. Electric prods must not be applied to any one WH&B more than three times during a procedure (e.g., sorting, loading) except in extreme cases with approval of the Lead COR/COR/PI. Each exception must be approved at the time by the Lead COR/COR/PI. (**majo**r)
    h. Any electric prod use that may be necessary must be documented daily by the Lead COR/COR/PI including time of day, circumstances, handler, location (trap site or temporary holding facility), and any injuries (to WH&B or human). (**major**)

V. TRANSPORTATION

A. General

1. All sorting, loading, or unloading of WH&Bs during gathers must be performed during daylight hours except when unforeseen circumstances develop and the Lead COR/CO/PI approves the use of supplemental light. (**major**)

2. WH&Bs identified for removal should be shipped from the temporary holding facility to a BLM facility within 48 hours. (minor)
    a. Shipping delays for animals that are being held for release to range or potential on-site adoption must be approved by the Lead COR/COR/PI. (**major**)
3. Shipping should occur in the following order of priority; 1) debilitated animals, 2) pairs, 3) weanlings, 4) dry mares and 5) studs. (minor)
4. Planned
5. transport time to the BLM preparation facility from the trap site or temporary holding facility must not exceed 10 hours. (**major**)
6. WH&Bs should not wait in stock trailers and/or semi-trailers at a standstill for more than a combined period of three hours during the entire journey. (minor)

B. Vehicles

1. Straight-deck trailers and stock trailers must be used for transporting WH&Bs. (**major**)
    a. Two-tiered or double deck trailers are prohibited. (**major**)
    b. Transport vehicles for WH&Bs must have a covered roof or overhead bars containing them such that WH&Bs cannot escape. (**major**)
2. WH&Bs must have adequate headroom during loading and unloading and must be able to maintain a normal posture with all four feet on the floor during transport without contacting the roof or overhead bars. (**major**)
3. The width and height of all gates and doors must allow WH&Bs to move through freely. (**major**)
4. All gates and doors must open and close easily and be able to be secured in a closed position. (**major**)
5. The rear door(s) of the trailers must be capable of opening the full width of the trailer. (**major**)
6. Loading and unloading ramps must have a non-slip surface and be maintained in proper working condition to prevent slips and falls. (**major**)

7. Transport vehicles more than 18 feet and less than 40 feet in length must have a minimum of one partition gate providing two compartments; transport vehicles 40 feet or longer must have at least two partition gates to provide a minimum of three compartments. (**major**)
8. All partitions and panels inside of trailers must be free of sharp edges or holes that could cause injury to WH&Bs. (**major**)
9. The inner lining of all trailers must be strong enough to withstand failure by kicking that would lead to injuries. (**major**)
10. Partition gates in transport vehicles should be used to distribute the load into compartments during travel. (minor)
11. Surfaces and floors of trailers must be cleaned of dirt, manure and other organic matter prior to the beginning of a gather. (**major**)

C. Care of WH&Bs during Transport Procedures

1. WH&Bs that are loaded and transported from the temporary holding facility to the BLM preparation facility must be fit to endure travel. (**major**)
    a. WH&Bs that are non-ambulatory, blind in both eyes, or severely injured must not be loaded and shipped unless it is to receive immediate veterinary care or euthanasia. (**major**)
    b. WH&Bs that are weak or debilitated must not be transported without approval of the Lead COR/COR/PI in consultation with the on-site veterinarian. Appropriate actions for their care during transport must be taken according to direction of the Lead COR/COR/PI. (**major**)
2. WH&Bs should be sorted prior to transport to ensure compatibility and minimize aggressive behavior that may cause injury. (minor)
3. Trailers must be loaded using the minimum space allowance in all compartments as follows: (**major**)
    a. 12 square feet per adult horse.
    b. 6.0 square feet per dependent horse foal.
    c. 8.0 square feet per adult burro.
    d. 4.0 square feet per dependent burro foal.

4. The Lead COR/COR/PI in consultation with the receiving Facility Manager must document any WH&B that is recumbent or dead upon arrival at the destination. (**major**)
    a. Non-ambulatory or recumbent WH&Bs must be evaluated on the trailer and either euthanized or removed from the trailers using a sled, slide board or slip sheet. (**major**)
5. Saddle horses must not be transported in the same compartment with WH&Bs. (**major**)

VI. EUTHANASIA OR DEATH

A. Euthanasia Procedure during Gather Operations

1. An authorized, properly trained, and experienced person as well as a firearm appropriate for the circumstances must be available at all times during gather operations. When the travel time between the trap site and temporary holding facility exceeds one hour or if radio or cellular communication is not reliable, provisions for euthanasia must be in place at both the trap site and temporary holding facility during the gather operation. (**major**)
2. Euthanasia must be performed according to American Veterinary Medical Association euthanasia guidelines (2013) using methods of gunshot or injection of an approved euthanasia agent. (**major**)
3. The decision to euthanize and method of euthanasia must be directed by the Authorized Officer or their Authorized Representative(s) that include but are not limited to the Lead COR/COR/PI who must be on site and may consult with the on-site/on-call veterinarian. (**major**)
4. Photos needed to document an animal's condition should be taken prior to the animal being euthanized. No photos of animals that have been euthanized should be taken. An exception is when a veterinarian or the Lead COR/COR/PI may want to document certain findings discovered during a postmortem examination or necropsy. (minor)
5. Any WH&B that dies or is euthanized must be documented by the Lead COR/COR/PI including time of day, circumstances, euthanasia method, location, a

description of the age, gender, and color of the animal and the reason the animal was euthanized. (**major**)

6. The on-site/on-call veterinarian should review the history and conduct a postmortem physical examination of any WH&B that dies or is euthanized during the gather operation. A necropsy should be performed whenever feasible if the cause of death is unknown. (minor)

B. Carcass Disposal

1. The Lead COR/COR/PI must ensure that appropriate equipment is available for the timely disposal of carcasses when necessary on the range, at the trap site, and temporary holding facility. (**major**)
2. Disposal of carcasses must be in accordance with state and local laws. (**major**)
3. WH&Bs euthanized with a barbiturate euthanasia agent must be buried or otherwise disposed of properly. (**major**)
4. Carcasses left on the range should not be placed in washes or riparian areas where future runoff may carry debris into ponds or waterways. Trenches or holes for buried animals should be dug so the bottom of the hole is at least 6 feet above the water table and 4-6 feet of level earth covers the top of the carcass with additional dirt mounded on top where possible. (minor)

CAWP

REQUIRED DOCUMENTATION AND RESPONSIBILITIES OF LEAD COR/COR/PI

Required Documentation

Section	Documentation
II.B.5	Helicopter contact with any WH&B.
II.C.2	Roping of any WH&B.
III.B.3.a and III.B.4.b	Reason for allowing longer than four hours to reunite foals with mares/jennies. Does not apply if foals are being weaned.
III.C.1	Health status of all saddle and pilot horses.
IV.C.2.h	All uses of electric prod.
V.C.4	Any WH&B that is recumbent or dead upon arrival at destination following transport.
VI.A.5	Any WH&B that dies or is euthanized during gather operation.

Responsibilities

Section	Responsibility
I.A.10	Approve materials used in construction of finger gates in bait trapping
II.A.1	Direct gather procedures using approved gather technique.
II.B. 2	Determine rate of movement and distance limitations for WH&B helicopter gather.
II.B.2.a	Direct appropriate gather/handling methods for weak or debilitated WH&B.
II.B.3	Determine whether to abandon pursuit or use other capture method in order to avoid repeated pursuit of WH&B.
II.B.4	Determine width and need for visibility marking when using opening in fence en route to trap.
II.B.6	Determine number of attempts that can be made to capture the missing half of a mare/foal pair that has become separated.
II.B.7	Determine whether to proceed with gather when ambient temperature is outside the range of 10°F to 95°F for horses or 10°F to 100°F for burros.
II.C.1	Approve roping of any WH&B.
II.D.1.a	Determine period of time that water outside a bait trap is inaccessible such that wellbeing of WH&Bs, wildlife, or livestock is not adversely affected.
III.A.2	Direct and consult with on-site/on-call veterinarian on any matters related to WH&B health, handling, welfare and euthanasia.

III.B.1.e	Adjust feed/water as necessary, in consultation with onsite/on call veterinarian, to provide for needs of animals when water or feed deprivation conditions exist on range.
III.B.4.c	Determine provision of water and hay to non-ambulatory animals.
IV.C.2.g	Approve use of electric prod more than three times, for exceptional cases only.
V.A.1	Approve sorting, loading, or unloading at night with use of supplemental light.
V.A.2.a	Approve shipping delays of greater than 48 hours from temporary holding facility to BLM facility.
V.C.1.b	Approve of transport and care during transport for weak or debilitated WH&B.
VI.A.3	Direct decision regarding euthanasia and method of euthanasia for any WH&B; may consult with on-site/on-call veterinarian.
VI.B.1	Ensure that appropriate equipment is available for carcass disposal.

PROPOSED CAWP COMPONENTS FOR OFF-RANGE CORRAL FACILITIES, TRANSPORTATION, AND ADOPTION EVENTS **22**

PREFACE

The Bureau of Land Management (BLM) estimates that 58,150 wild horses and burros (WH&Bs) are roaming on BLM-managed rangelands in 10 Western states, based on the latest data available, compiled as of March 1, 2015. Wild horses and burros have virtually no natural predators and their herd sizes can double about every four years. As a result, the agency must remove thousands of animals from the range each year to control herd sizes.

The Bureau of Land Management manages many off-range corral facilities throughout the U.S. The primary mission of the off-range corral facilities is to act as a holding and preparation facility that accepts WH&Bs from gather/removal operations and prepares them for adoption to the public or placement into off-range pastures. As of November 2015, there are 16,182 WH&Bs in off-range corral facilities.

The design of each facility is organized to handle large numbers of WH&Bs with pens, corrals, alleys, and loading/unloading areas that facilitate animal movement. There are multiple pens and corrals to sort animals for compatibility and care upon arrival to the facility. Each pen or corral offers all animals continuous water accessibility and quality feed on a daily basis.

The BLM strives to place horses removed from the range into private homes that provide quality care. Horses placed in off-range corral facilities are made available to the public for adoption or sale at adoption events held throughout the U.S. and through the BLM's Adopt or Sales Program (http://www.blm.gov/wo/st/en/prog/whbprogram/adoption_program/schedule.html). The off-range corral facility transitions WH&Bs to hay diets, performs necessary vaccinations and deworming procedures, provides hoof care and may train WH&Bs. Other WH&Bs, due to age, temperament, or other factors, may not be adopted or sold and subsequently are placed in off-range pastures. These facilities are designed to provide unadoptable wild horses with humane life-long care in a natural setting off the public rangelands. There are approximately 46,016 WH&Bs being cared for in off-range pastures (November 2015). All WH&Bs residing in both off-range corral facilities and off-range pastures, like those roaming Western public rangelands, are protected by the BLM under the 1971 Wild Free-Roaming Horses and Burros Act, as amended.

The BLM has been criticized by the public and animal protection organizations on their handling and care of wild horses and burros especially during the gathering activities and transitioning of the horses from public lands to off-range facilities. Some of the issues include the transportation conditions of the horses, facility design, environmental conditions, handling practices, and nutrition. Agricultural and research animal industries have developed assessment or auditing programs to verify humane care and handling of their industry's animals. These industries are performing both internal and 3rd-party audits for animal welfare to assure their stakeholders and provide transparency on how these animals are provided care and proper handling. Assessment programs based on standards have multifaceted benefits in providing education to employees and assurance to societal entities that their programs are responsible for properly handling and providing care for the animals. An assessment welfare program reported routinely to the public will increase transparency concerning the humane treatment of BLM's WH&Bs, as recommended by the 2008 US Government Accountability Office.

STANDARDS

Deficiency Definitions

Major Deficiency: impacts welfare of WH&Bs; usually is a procedure. Appropriate wording is "must," "unacceptable," "prohibited."

Minor Deficiency: a reporting deficiency (lack of, not enough detail) or involves an uncontrollable situation. Appropriate wording is "should."

WH&Bs = Wild horses and burros

SECTION 1.

OFF-RANGE CORRAL FACILITY STANDARDS

I. FACILITY PERSONNEL

A. Facility management establishes and implements standards of care, treatment, and handling of WH&Bs, and communicates expectations to all personnel to ensure the humane care and treatment of all WH&Bs at the facility. (**major**)

B. The facility must have employees with training, skills, and experience to observe, move, and handle the WH&Bs on the facility. (**major**)

C. The facility must have personnel that can properly maintain the working chute systems and facility infrastructure to provide for the safe housing, movement, and processing of the WH&Bs. (**major**)

D. The facility should be staffed by appropriate office staff for record maintenance and recording. (minor)

II. FACILITY DESIGN

A. Facilities must be operated in a manner to provide a safe, clean and supportive environment for all WH&Bs. (major)

B. WH&Bs must be allowed to exist in an undisturbed environment unless being prepared for health procedures, identification, adoption events, or transportation. (major)
C. All WH&Bs must have adequate space to move freely within a pen enclosure. (major)
D. The facility must have a sufficient number of pens available to sort WH&Bs according to sex, age, temperament, health status, or physical condition as needed. (major)
E. Facility fences, gates, alleys, tubs, and working chutes must be constructed of stout materials and must be maintained in proper working condition. (major)
F. Fences in pens, alleys, and working chute systems must be not less than 6 feet high for horses, 5 feet high for burros, and the bottom rail must not be more than 12 inches from ground level. (major)
G. Fences must be of stout design and be maintained in proper condition with no holes, gaps, or sharp edges which could result in WH&Bs being injured. (major)
H. All WH&Bs within a pen must have adequate dry space to rest. (major)
I. Ground surfaces in pens must be maintained to promote drainage, reduce wet ground conditions, and allow for routine manure removal. (major)
J. Watering systems in WH&B holding pens must provide unlimited access to clean water appropriate for livestock at all times. (major)
K. Feeding areas must be accessible to all WH&Bs in the enclosure and maintained as a dry area without excessive manure accumulation. (major)
L. An appropriate squeeze chute maintained in proper working order must be available for safely restraining WH&Bs for necessary procedures at the facility including hoof trimming. (major)
M. Facilities must provide access to shade and shelter (wind breaks) in pens designated for compromised animals needing special care (i.e., injured or weak animals). Additional provisions for shade and shelter (wind breaks) will be evaluated and determined by managers as appropriate for their region, the function of their facility and the condition of the animals under their care. (major)

N. Shelter structures should be designed or constructed to reduce the risk for injury of the WH&Bs and maintained to avoid excessive manure and mud. (minor)

III. RECEIVING WILD HORSES AND BURROS

A. Loading and Unloading Facilities

1. Facilities in areas for loading and unloading WH&Bs must be maintained in a safe and proper working condition, including gates and doors that swing freely and latch or tie easily as designed. (**major**)
2. The side panels of the loading chute must be a minimum of 6 feet high and covered with materials such as plywood or metal without holes that may cause injury. (**major**)
3. There must be no holes, gaps or openings, protruding surfaces, or sharp edges present in fence panels or other structures that may cause escape or possible injury. (**major**)
4. Loading and unloading ramps must have a non-slip surface and be maintained in a safe and proper working condition to prevent slips and falls. Examples of non-slip floors would include, but not be limited to, rubber mats, sand, shavings, and steel reinforcement rods or rough surfaces built into the ramp. There must be no holes in flooring or items that cause an animal to trip. (**major**)
5. Trailers must be properly aligned with loading and unloading chutes and panels with no gaps between the chute/panel and floor or sides of the trailer creating a situation where a WH&B could injure itself. (**major**)
6. Stock trailers should be positioned for loading and unloading such that there is no more than 12" clearance between the ground and floor of the trailer for burros and 18" for horses. (minor)

B. Receiving Procedures

1. All unloading of WH&Bs must be performed during daylight hours except when unforeseen circumstances develop and the Authorized Officer approves of the use of supplemental light. (**major**)

2. At the time of unloading, WH&Bs must be inspected by facility personnel to look for signs of infectious disease, sickness or injury and take appropriate steps if these conditions are observed. (**major**)
3. Any WH&B needing immediate veterinary attention must be identified and separated as necessary for examination, and a consultation with a veterinarian must be conducted within 4 hours. (**major**)
4. An authorized, properly trained, and experienced person, as well as euthanasia equipment and supplies, must be available immediately following unloading in the event that the emergency euthanasia of an animal is required. Euthanasia must be done in compliance with BLM Euthanasia policy. (**major**)
5. The receiving Authorized Officer must document any WH&B that is recumbent or dead upon arrival at the destination. (**major**)
6. Reporting of animals received from gather operations or from another BLM facility must be done in compliance with BLM policy. (**major**)
7. WH&Bs received from a gather must remain segregated from resident animals at the facility until a negative test for Equine Infectious Anemia (EIA) can be confirmed. (**major**)
8. Newly arrived WH&Bs must immediately be provided hay and water upon unloading. (**major**)
9. When WH&Bs are received from gather operations or from another facility, the receiving facility should unload them in a manner to minimize stress. (minor)
10. WH&Bs should be penned with WH&Bs of like age, sex, and temperament. (minor)
11. Newly arrived WH&Bs should be observed for signs that they may have difficulty transitioning to hay in a domestic setting. (minor)

IV. CARE OF WILD HORSE AND BURROS

A. Veterinarian

1. Routine presence by an on-site or on-call veterinarian must be provided at each facility with records of those visits maintained at the facility. (**major**)
2. A veterinarian must be available to collect and submit blood samples for Equine Infectious Anemia (EIA) testing and rabies immunization. (**major**)
3. Health care protocols must be in accordance with Program guidelines and accepted by the facility veterinarian for preventive health care procedures (vaccinations, deworming, hoof trimming, freeze marking). Medical treatments will be prescribed by or performed under the supervision of a veterinarian. Surgical procedures will only be performed by a veterinarian. (**major**)
4. WH&B deaths in a facility should be discussed with the facility veterinarian to review the probable causes of death. (minor)
5. If multiple animals die due to a related cause or unknown cause(s), a post-mortem examination or necropsy should be performed by the facility's on-call or on-site veterinarian to identify the cause of death where possible. Laboratory testing should be performed when possible to aid in determining the cause of death or related underlying factors that may be present when these are not readily apparent during the gross examination. (minor)
6. If a series of unexplained deaths occurs, facility quarantine measures must be considered with input from the attending veterinarian until the cause has been determined or when indicated until adequate bio-security measures are in place to prevent the spread of disease. Coordination with State and/or Federal Animal Health Officials in consultation with the attending veterinarian must be done if this occurs. (**major**)

B. Bio-Security

1. Authorized Officers must consult with the on-site or on-call veterinarian(s) to establish and review biosecurity and health care decisions. (**major**)

2. Newly arrived WH&Bs from gather operations must not be co-mingled with resident animals at the facility. (**major**)
3. Pens should be provided to segregate sick, infectious, injured, or weak WH&Bs from other healthy individuals in the facility when possible. (minor)
4. Hazardous or infectious biological waste (i.e., sharps, needles, blood samples, etc.) must be properly disposed in labeled containers. (**major**)
5. Working chute and tub systems should be routinely cleaned and disinfected to reduce the risk of disease transmission, especially after moving contagious WH&Bs through the system. (minor)

C. Feed and Water

1. Quality hay must be provided daily to WH&Bs in the amount of 2-3% of their body weight per day. **(major)**
2. Fresh, clean water appropriate for livestock must be accessible to WH&Bs located in holding pens at all times. (**major**)
3. Water troughs and watering systems must be checked daily to ensure they are clean and operating correctly. (**major**)
4. Feeding sites must allow all WH&Bs within a pen simultaneous access to hay. (**major**)
5. Newly arrived WH&Bs from gather operations may be fed grass hay and transitioned to alfalfa. (minor)
6. Salt and/or mineral blocks should be provided in holding pens at all times. (minor)
7. Supplemental feeds should be provided to address the nutritional needs of the WH&Bs, if needed. (minor)

D. Preparation Procedures

1. Facilities must identify individual WH&Bs and maintain inventories in accordance with BLM policy. This includes unmarked WH&Bs as well as those provided a freeze-mark. **(major)**
2. Facilities must conduct Equine Infectious Anemia (EIA) testing and apply freeze-marks within 30 days of receiving WH&Bs, unless directed by the facility veterinarian when age or physical condition requires a delay. (**major**)

3. WH&Bs receiving a freeze-mark must be recorded on the animal preparation record using the approved Signalment Key. (**major**)
4. Foals born in the facility should be freeze-marked no earlier than 3 months of age. (minor)
5. WH&Bs must be evaluated daily by facility personnel to identify animals in poor body condition, poor hoof condition, injured, or in need of veterinary evaluation/treatment, and/or supplemental feeding. (**major**)
6. Facilities must adhere to the current BLM vaccination policy. (**major**)
7. Foals must be tested for EIA and vaccinated when weaned or at 6 months of age. (**major**)
8. Hoof trimming must be performed twice per year at minimum or as necessary to maintain hooves in a proper condition. (**major**)
9. Castration of stallions and jack burros must be performed by a veterinarian using general anesthesia. If a surgical plane of anesthesia is not reached initially animals must be re-dosed or the procedure postponed until the problem can be resolved. (**major**)
10. Stallions and jack burros should be castrated as soon as approved by the on-site veterinarian for the procedure in accordance with BLM policy. (minor)
11. WH&Bs being prepared for freeze-marking, blood collection, vaccination, hoof trimming, sorting, and other care treatments should be handled to minimize stress and injuries (minor).

E. Euthanasia Procedures

1. The decision to euthanize and method of euthanasia must be directed by the Authorized Officer(s) who may consult with the on-site/on-call veterinarian. (**major)**
2. Euthanasia must be done in compliance with BLM Euthanasia policy. (**major**)
3. An authorized, properly trained, and experienced person, as well as euthanasia equipment and supplies, must be available at off-range corral facilities in the event that the emergency euthanasia of an animal is required. (**major**)

4. Any WH&B that dies or is euthanized must be documented including the circumstances, freeze brand ID if present, a description of the age, sex, color of the animal and the reason the animal was euthanized. A death record must be entered into the WHBPS. (**major**)
5. If an animal is euthanized due to an unknown cause, a post-mortem examination or necropsy should be performed by the facility's on-call or on-site veterinarian to identify the cause of death where possible. Laboratory testing should be performed when possible to aid in determining the cause of death or related underlying factors that may be present when these are not readily apparent during the gross examination. (minor)

F. Carcass Disposal

1. The Authorized Officer must ensure that appropriate procedures are in place for the timely disposal of carcasses when necessary at off-range corral facilities. (**major**)
2. Disposal of carcasses must be in accordance with applicable state and local laws. (**major**)

V. HANDLING WILD HORSES AND BURROS

A. Willful Acts of Abuse

1. Hitting, kicking, or beating any WH&Bs in an abusive manner is prohibited. **(major)**
2. Dragging a recumbent WH&Bs without a sled, side board or slip sheet is prohibited. Ropes used for moving the recumbent animal must be attached to the sled, slide board, or slip sheet. (**major**)
3. There should be no deliberate driving of WH&Bs into other animals, closed gates, panels, or other equipment. (minor)
4. There should be no deliberate slamming of gates and doors on WH&Bs. (minor)
5. There should be no excessive noise (e.g., constant yelling) or sudden activity causing WH&Bs to become unnecessarily flighty, disturbed or agitated. (minor)

B. General Handling

1. All sorting, loading or unloading of WH&Bs must be performed during daylight hours except when unforeseen circumstances develop and the Authorized Officer approves of the use of supplemental light. (**major**)
2. Halters and ropes tied to a WH&B may be used to roll, turn, position, or load a recumbent animal, but a WH&B must not be dragged across the ground by a halter or rope attached to its body while in a recumbent position. (**major**)
3. WH&Bs should be moved into and out of pens in a manner that will minimize stress and injury. (minor)
4. When possible, WH&Bs should be allowed to move at their own pace to new pens or sorting/handling locations. (minor)
5. WH&Bs should be handled to enter runways or chutes in a forward direction. (minor)
6. Any unattended WH&Bs or a single WH&B should not remain in single-file alleyways, runways or chutes longer than 30 minutes. (minor)
7. No equipment should be operated in such a manner as to cause flighty behavior or injury to WH&Bs. (minor)

B. Handling Aids

1. Handling aids such as flags and shaker paddles must be the primary tools for driving and moving WH&Bs during handling and transport procedures. Contact of the flag or paddle end of primary handling aids with a WH&B is allowed. Ropes looped around the hindquarters may be used from horseback or on foot to assist in moving an animal forward or during loading. **(major)**
2. Electric prods must not be used routinely as a driving aid or handling tool. Electric prods may be used in limited circumstances only if the following guidelines are followed:
    a. Electric prods must only be a commercially available make and model that uses DC battery power with batteries fully charged at all times. (**major**)
    b. The electric prod device must never be disguised or concealed. (**major**)

c. Electric prods must only be used after three attempts using other handling aids (flag, shaker paddle, voice or body position) have been tried unsuccessfully to move the WH&Bs. (**major**)
d. Electric prods must only be picked up when intended to deliver a stimulus; these devices are not constantly carried by the handlers. (**major**)
e. Space in front of an animal should be available for the WH&B to move forward prior to application of the electric prod. (**major**)
f. Electric prods must never be applied to the face, genitals, anus, or underside of the tail of a WH&B. (**major**)
g. Electric prods must not be applied to any one WH&B more than three times during a procedure (e.g., sorting, loading) except in extreme cases with the approval of the Authorized Officer. Each exception must be approved at the time by the Authorized Officer. (**major**)

SECTION 2.

TRANSPORTATION STANDARDS TO ANOTHER OFF-RANGE CORRAL FACILITY, OFF-RANGE PASTURE, ECO-SANCTUARY OR ADOPTION EVENT

I. LOADING AND UNLOADING FACILITIES

A. Facilities in areas for loading and unloading WH&Bs must be maintained in a safe and proper working condition, including gates and doors that swing freely and latch or tie easily as designed. (**major**)

B. The side panels of the loading chute must be a minimum of 6 feet high and covered with materials such as plywood or metal without holes that may cause injury. (**major**)

C. There must be no holes, gaps or openings, protruding surfaces, or sharp edges present in fence panels or other structures that may allow escape or cause possible injury. (**major**)

D. Loading and unloading ramps must have a non-slip surface and be maintained in a safe and proper working condition to prevent slips and falls. Examples of non-slip floors would include, but not be limited to, rubber mats, sand, shavings, and steel reinforcement rods or rough surfaces built into the ramp. There must be no holes in flooring or items that cause an animal to trip. (**major**)

E. Trailers must be properly aligned with loading and unloading chutes and panels with no gaps between the chute/panel and floor or sides of the trailer creating a situation where a WH&B could injure itself. (**major**)

F. Stock trailers should be positioned for loading and unloading such that there is no more than 12” clearance between the ground and floor of the trailer for burros and 18” for horses. (minor)

II.CARE OF WILD HORSES AND BURROS DURING TRANSPORT PREPARATION PROCEDURES

A. WH&Bs being transferred to another off-range corral facility, off-range pasture, eco-sanctuary or adoption event must have a current negative EIA test, be in a state of health appropriate for a Certificate of Veterinary Inspection (CVI), and be accompanied by appropriate paperwork as required by the laws of the receiving state. **(major)**

B. WH&Bs being transferred to another off-range corral facility, off-range pasture, eco-sanctuary or adoption event must be fit to endure the travel. (**major**)

    1. WH&Bs that are non-ambulatory, blind in both eyes, or severely injured must not be loaded and shipped unless it is to receive immediate veterinary care or euthanasia (**major**)

    2. WH&Bs that are weak or debilitated must not be transported without the approval of Authorized Officer in consultation with the on-site veterinarian. Appropriate actions for their care during transport must be taken according to the Authorized Officer. (**major**)

C. WH&Bs being transferred to another off-range corral facility, off-range pasture, eco-sanctuary, or adoption event must be sorted prior to shipping to ensure compatibility and minimize aggressive behavior that may cause injury during transport. (**major**)

D. Except for exceptional circumstances including but not limited to trap site adoptions, WH&Bs being offered for adoption should have received primary and booster vaccinations as well as deworming medications prior to adoption. (minor)

II. VEHICLES

A. Straight deck trailers or stock trailers must be used for transporting WH&Bs to another off-range corral facility, off-range pasture, eco-sanctuary or adoption event. **(major)**

    1. Two-tiered or double deck trailers are prohibited. **(major)**
    2. Transport vehicles for WH&Bs must have a covered roof containing them such that WH&Bs cannot escape. **(major)**

B. WH&Bs must have adequate headroom during loading and unloading and must be able to maintain a normal posture with all four feet on the floor during transport without contacting the roof. **(major)**

C. The width and height of all gates and doors must allow WH&Bs to move through freely. **(major)**

D. All gates and doors must open and close easily and be able to be secured in a closed position. **(major)**

E. Loading and unloading ramps of vehicles must have a non-slip surface and be maintained in a safe and proper working condition to prevent slips and falls. Examples of non-slip flooring would include, but not be limited to, rubber mats, sand, shavings, and steel reinforcement rods built into ramp. There must be no holes in the flooring or items that can cause an animal to trip. **(major)**

F. Transport vehicles more than 18 feet and less than 40 feet in length must have a minimum of one partition gate providing two compartments; transport vehicles 40 feet or longer must have at least two partition gates to provide a minimum of three compartments. **(major)**

G. Partition gates in transport vehicles should be used to distribute the load into compartments during travel. (minor)

H. All partitions and panels inside of trailers must be free of sharp edges or holes that could cause injury to WH&Bs. **(major)**

I. The inner lining of all trailers must be strong enough to withstand failure by kicking that would lead to injuries. **(major)**

J. Surfaces and floors of trailers must be cleaned of dirt, manure and other organic matter prior to the beginning of a shipping event, and must have non-skid material on the trailer floor, such as, wood shavings, rubber non-skid mats etc. **(major)**

III. TRANSPORT PROCEDURES

A. WH&Bs must be loaded at the following rates: **(major)**

1. 12 square feet per adult horse.
2. 6.0 square feet per dependent horse foal.
3. 8.0 square feet per adult burro or yearling horse.

4. 4.0 square feet per dependent burro foal

B. Planned drive time from off-range corral facility to another off-range corral facility, off-range pasture, eco-sanctuary, or adoption must not exceed 24 hours without unloading. (**major**)

C. Trucking companies or haulers must be provided directions and contact phone numbers for the facility or adoption location. **(major**)

D. A transportation event that is longer than 24 hours will require unloading and a minimum rest period of 8 hours with access to hay and water prior to being re-loaded and sent to the final destination. **(major**)

E. While in transit, WH&Bs must be observed by the transport driver a minimum of once every 8 hours. **(major)**

F. Non-ambulatory or recumbent WH&Bs must be evaluated on the trailer and either euthanized or removed from the trailers using a sled, slide board or slip sheet. (**major**)

G. WH&Bs should not be allowed to remain standing on straight-deck and stock trailers while not in transport for a combined period of greater than three (3) hours. (minor)

IV. RECEIVING PROCEDURES

See Section 1. Off-range Corral Standards, Part III. B. 1-5 and 8-11.

SECTION 3.

ADOPTION EVENT STANDARDS

I. ADOPTION EVENT PERSONNEL

A. BLM establishes and implements standards of care, treatment, and handling of WH&Bs, and communicates expectations to all personnel to ensure the humane care and treatment of all WH&Bs at the adoption event. **(major)**

B. The adoption event must have employees with training, skills, and experience to observe, move, and handle the WH&Bs at the event. **(major)**

C. The adoption event must have maintenance staff that can properly maintain the facilities to provide for the safe housing, movement, and processing of the WH&Bs. **(major)**

II. SATELLITE FACILITY DESIGN

A. All satellite facilities must be operated in a manner to provide a safe, clean and supportive environment for all WH&Bs. **(major)**

B. The satellite facility must have a sufficient number of pens available to sort WH&Bs according to sex, temperament, or physical condition as needed. (**major**)

C. The satellite facility's fences, gates, alleys, and working chutes must be constructed of stout materials and must be maintained in proper working condition. (**major**)

D. Fences in adoption pens, alleys, and working chute systems must not be less than 6 feet high for horses and 5 feet high for burros. (**major**)

E. Adoption pen fences must be of stout design and must be maintained in proper condition with no holes, gaps, or sharp edges that could result in WH&Bs being injured. (**major**)

F. Watering systems in WH&B adoption holding pens must provide unlimited access to clean water appropriate for livestock at all times. (**major**)

G. Adoption pen feeding areas must be accessible to all WH&Bs in the pen at the same time. (**major**)

H. Ground surfaces in adoption pens should promote drainage to reduce wet ground conditions. (minor)

I. WH&Bs in pens at the satellite facility should be maintained at a stocking density such that when at rest all WH&Bs occupy no more than half the pen area. (minor)

III. CARE OF WILD HORSES AND BURROS RECEIVED AT SATELLITE FACILITIES

A. Provisions to provide care by a veterinarian in a timely manner on-site, on call, or by transporting an animal to a veterinarian must be made in advance**. (major)**

B. Provisions for medical care (treatments including euthanasia if necessary) at adoption events will be made in accordance with BLM policy and carried out as described above for preparation facilities (Section 1. Off-range Corral Facility Standards, Part IV. A. 1-6). (**major**)

C. WH&Bs must be sorted upon arrival at adoption events into pens with animals of appropriate age and temperament such that animals can promptly begin a period of rest, eating, and drinking with limited disturbance. **(major)**

D. All WH&Bs must have adequate space to move freely within an adoption facility pen. **(major)**

E. WH&Bs, to the greatest extent possible, must be allowed to exist in an undisturbed environment after arriving at an adoption facility until the adoption event begins. **(major)**

F. Quality hay must be provided to WH&Bs in the amount of 2-3% of their body weight per day upon unloading following transport and daily during the adoption event. **(major)**

G. WH&Bs at adoption events may be supplemented with feed or water supplements to address the stress of transport. (minor)

H. WH&Bs will be sorted during the adoption event in a manner to reduce stress and opportunity for injury. (minor)

I. WH&Bs transported for more than 12 hours to an adoption event should be allowed a rest period of 5 hours or more prior to formal viewing by the adopting public. (minor)

IV. EUTHANASIA PROCEDURES AT SATELLITE FACILITIES

See Section 1. Off-range Corral Facility Standards, Part IV. E. 1-4.

V. CARCASS DISPOSAL AT SATELLITE FACILITIES

See Section 1. Off-range Corral Facility Standards, Part IV. F. 1-2.

VI. HANDLING WILD HORSES AND BURROS AT SATELLITE FACILITIES

A. Willful Actus of Abuse

See Section 1. Off-range Corral Facility Standards, Part V. A. 1-5

B. General Handling

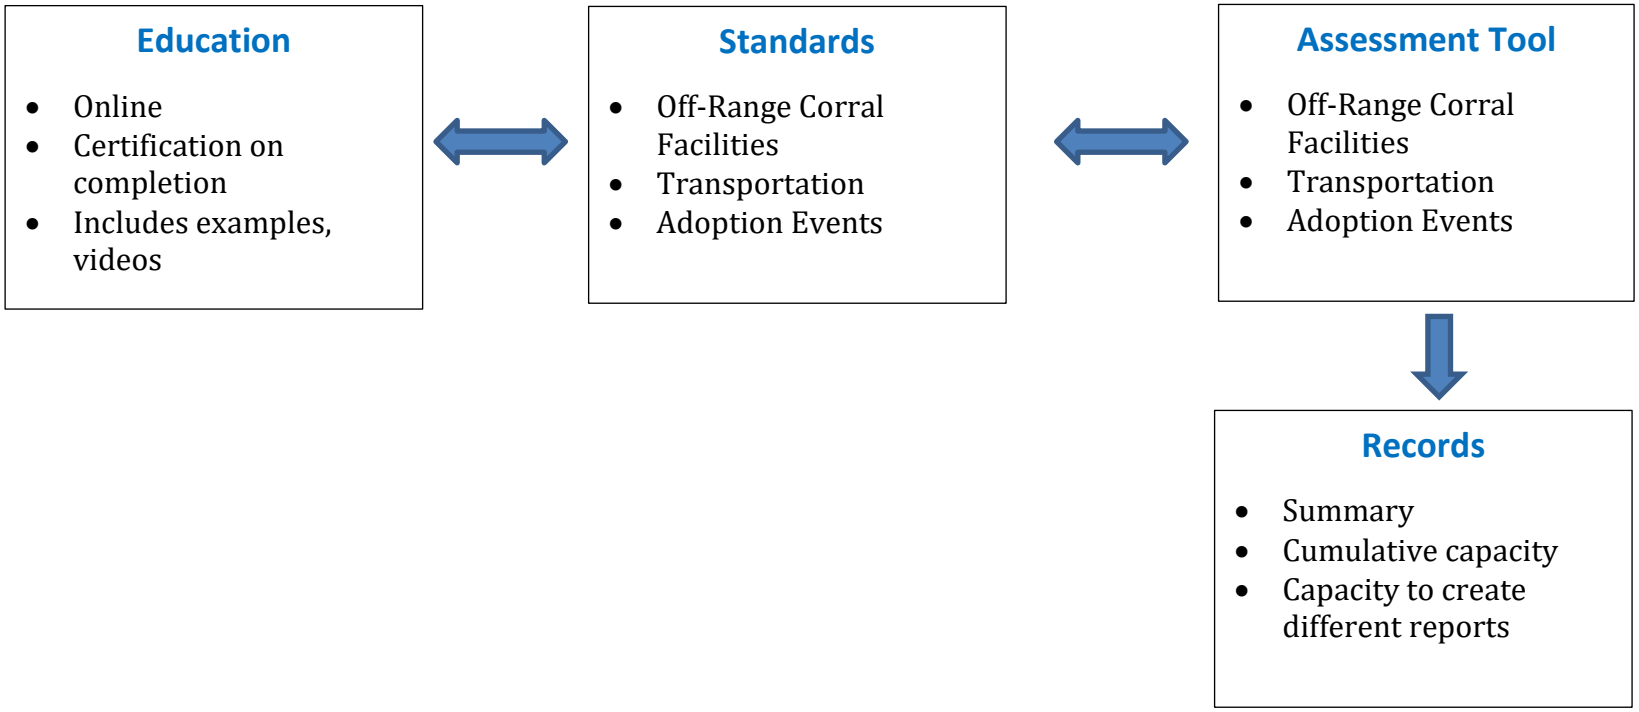
See Section 1. Off-range Corral Facility Standards, Part V. B. 1-7

C. Handling Aids

See Section 1. Off-range Corral Facility Standards, Part V. C. 1-2

REQUIRED DOCUMENTATION AND RESPONSIBILITIES OF AUTHORIZED OFFICERS

REQUIRED DOCUMENTATION



STANDARD	DOCUMENTATION
Section 1	**Off-Range Corral Facility Standards**
Part III. B. 5	Any WH&B that is recumbent or dead upon arrival at the destination
Part IV. A. 1	Record of visits by on-site/on-call veterinarian
Part IV. E. 4	Any WH&B that dies or is euthanized at facility, including the circumstances, freeze brand ID if present, a description of the age, sex, color of the animal and the reason the animal was euthanized. A death record must be entered into the WHBPS.
Section 2	**Transportation Standards**
Part V	Refer to Section 1. Off-range Corral Facility Standards, Part III. B. 5, as above.
Section 3	**Adoption Event Standards**
Part IV	Refer to Section 1. Off-range Corral Facility Standards, Part IV. E. 4, as above

RESPONSIBILITIES

STANDARD	RESPONSIBILITY
Section 1	**Off-Range Corral Facility Standards**
Parts III. B. 1 & V.B.1	Approve use of supplemental lighting when sorting, loading, or unloading WH&Bs
Part III. B. 5	Document any WH&B that is recumbent or dead upon arrival at the destination
Part IV. B. 1	Consult with on-site/on-call veterinarian to establish and review biosecurity and health care decisions
Part IV. E. 1	Direct decision regarding euthanasia and method of euthanasia for any WH&B; may consult with on-site/on-call veterinarian
Part IV. F. 1	Ensure that appropriate procedures are in place for carcass disposal
Part V. C. 2. g	Approve use of electric prod more than three times, for exceptional cases only

STANDARD	RESPONSIBILITY
Section 2	**Transportation Standards**
Part II. D	Approve of transport and care during transport for weak or debilitated WH&B
Section 3	**Adoption Event Standards**
Part VI. B	Refer to Section 1. Off-range Corral Facility Standard, Part IV.B.1, above.
Part VI. C	Refer to Section 1. Off-range Corral Facility Standard, Part V.C.2.g, above.

Harvesting antler velvet

From Mr D. J. Thomas

SIR,—With regard to the harvesting of antler velvet, I feel that the veterinary profession should once and for all condemn this practice, which is, most importantly, of no advantage to the animal concerned and the product harvested of unproven medical value. The only advantage which I can deduce is a financial one to the harvesters and marketers of this commodity.

I object to being told by people who are out to make a financial gain from this practice what we as a profession "must" do to further this unnecessary mutilation. I am confident that the profession in this country will not support this unnecessary practice.

B bronchiseptica vaccine

From Mr J. M. Phillips

SIR, The paper by C. J. Giles and others (Veterinary Record, January 12, 1980) provides an excellent insight into the role of *Bordetella bronchiseptica* in cases of infectious atrophic rhinitis (IAR) of pigs. I would like, through the courtesy of your columns, to comment on certain aspects of this work as they relate to the recently authorised *B bronchiseptica* vaccine (AR-PAC: Mycofarm).

I fully agree with the authors that the introduction of this vaccine will not provide an automatic answer to the problem and it most certainly should not be considered as obviating regimes of good management and hygiene. However, I feel that the author's comments regarding medication should be clarified. The pattern of *B bronchiseptica* infection is confirmed as occurring, in general, early in life (day one) and persisting for several weeks although "suppression" may delay overt infection. The most efficacious antibiotic medication programmes are those which provide therapeutic levels respective to the resistance of *B bronchiseptica* throughout this danger period. The full vaccination programme recommended for AR-PAC provides immunity to *B bronchiseptica* during this same period and indeed up until slaughter. In addition, a suppression of the carrier state of infected pigs is observed.

I consider, therefore, that AR-PAC provides a rational alternative to continuous medication programmes and satisfies the observation of Giles and others that continued control of IAR is best served by immunological rather than chemoprophylactic measures.

Price increase

From Mr D. C. North

SIR, — A lot has been written and said recently about the effects of the Medicines Act in removing old established products from the veterinary surgeon's shelves. It now appears that some companies are pricing themselves off the shelves. I have just received an invoice from my wholesaler which shows that the price of Norderm (Smith Kline) has increased by 400 per cent since I last ordered some three months ago. The selling price now works out about the same as a very good brandy — I just hope that the average dog fully appreciates this nectar.

D. C. NORTH
211 High Street,
Sheerness, Kent

A spokesman from Smith Kline comments: "From 1972 to 1978, although manufacturing and raw material costs of Norderm increased more than background inflation, the professional price in no way reflected this. In fact, price rises were very much less than inflation. By 1979 we were faced with a product being sold at a loss and suddenly increasing manufacturing and raw material costs. A very difficult decision had to be made whether to discontinue the product altogether or revise its price to an economic level. It now costs 5p a day to give Norderm to a 50 lb dog which we feel still represents very good value and we hope that this action will enable us to continue providing Norderm at good value."

RCVS appeal: The "Hundred Club"

From Miss W. M. Brancker and others

SIR,—Members will, by now, have read the letter from the President of the Royal College which was included as an insert in the Veterinary Record of January 19. We would like to commend to all our colleagues in the profession his plea that an increase in the staff and accommodation at Belgrave Square is urgently needed and that it should be the responsibility of the profession to raise the greater part, if not indeed all, of the capital sum required.

With a membership of 10,000 the Royal College could have raised the necessary money by a levy on each member of £20—but clearly this would be unfair on the new graduate and the retired. The College therefore, by implication, places its trust in the generosity of those of its members who can afford to make contributions of a substantial nature.

We believe that many senior members could make a donation of £100 towards the necessary extension of their Royal College and we ourselves have already made such a contribution. Can we appeal to as many of our colleagues as possible to join us in participating in membership of an informal "Hundred Club" so that we can meet the necessary target and meet it quickly? There are something of the order of 1,600 practices in this country and over 4,000 principals—so the requisite number of Hundred Club cheques ought not to be impossible to find; they should be sent to the President of the Royal College.

MSc in meat science (Bristol)

From Dr R. N. Smith

SIR,—The remarks attributed to me on p41 of the Veterinary Record of January 12 do not accord with what I believe I said at the meeting of Council on November 28. Certainly I would not have referred to the full-time MSc course at this university as "modular". Further, I expressed disappointment at the poor support from the profession, not from practitioners.

Of the 12 participants in the two years the course has now been in exisence only two are members of the Royal College and two others have veterinary qualifications from the Middle East. There are now many non-veterinary graduates with an interest in meat who are eligible for this type of course. Three of the remaining eight participants quote work with local authorities as part of their postgraduate experience (authorised meat inspector, environmental warden, public health inspector).

Park Row, Bristol

Libidinous behaviour in a gelding

From Mr S. Borsberry

SIR,—Some time ago I was presented with a 10-year-old pony gelding which had experienced a change in behaviour. During a period of 11 months the pony had been moved four times: (a) mixed grazing, mares and geldings, (b) only geldings present, (c) only geldings present and (d) mixed grazing, mares with geldings.

The pony had been at (a) for about six years and there had been no complaints as regards its behaviour. It was easy to ride and catch. For the sake of convenience it was moved to (b) on September 6, 1976 but unfortunately on January 15, 1977 the gelding started to break out and visit neighbouring mares. The owners of the field asked the owner to move him so she did to (c) on February 26, 1977. The situation eased but in April 1977 he began to visit mares again.

On May 12, 1977 he was moved to (d) where he became very difficult to catch, protective towards "his" mares and somewhat dangerous to ride. During this period he began to serve the mares. Palpation of the scrotal region revealed no abnormalities so it was decided to implant a 500 mg stilboestrol pellet. The rationale behind this was to reduce the male sexual behaviour with the female hormone. Unfortunately the opposite occurred; after about six days his sexual appetite increased considerably. It was then decided to explore surgically the inguinal region but there were no signs of cystic cords, testes or anything to suggest that he had not been gelded correctly as a yearling. The stilboestrol implant was removed at the same time.

Somewhat perplexed I rang John Cox at Liverpool University who suggested that this change in behaviour might be psychological and advised, if possible, to return the animal to (a). This was duly carried out and within three to four days the gelding had settled down, showed no interest in mares and was easy to catch, and has remained so.

BSAVA "fund run"

From Mr C. P. DeVile

SIR, — The BSAVA has entered the 1980s confident of its ability to provide monies for small animal research in a decade in which it is not difficult to forecast that the universities will be increasingly short of funds.

The fund receives magnificent support from members of the profession and on behalf of the management committee I thank all those colleagues who give time and energy in the organisation of fund raising events, those who donate fees due to them for lecturing and journalism, and our collecting box holders.

Collecting boxes are now available again, on application to Mr D. R. Highet, 410 Eaton Road, Liverpool L12 3HG.

Finally, sir, I would like to invite you and your readers to participate in a unique fund raising "exercise" that is planned to take place at BSAVA Congress in April. A sponsored "fun-run" (or Fund-run) will take place at the White City Stadium at a time that is guaranteed not to interfere with the other pleasures of congress. Sponsorship forms and full details will be sent to BSAVA members with their congress mailing, and to all non-members who register to attend. I give this advance notice of the event so that readers may have an opportunity to get into training. By carrying out their domiciliary visits by jog between now and April they will not only improve their performance at the White City but will make in addition a positive contribution to the energy crisis, though possibly creating one of their own.

C. P. DeVILE
Chairman, Management Committee,
BSAVA Clinical Studies Trust Fund

Letters may be shortened for publication

Postscript

Welfare motives

THE welfare of animals has become a matter of increasing concern in recent years, yet this has always been a subject of intense human interest; and so it should be. It is instructive to contemplate the three historic reasons why animal welfare is important to us.

The first is the pragmatic knowledge that, if animals are not cared for, they do not produce the results which their owners and beneficiaries require from them.

The second is the feeling of guilt, that we are debasing our own characters by association with neglectful or harmful actions leading to criticism by our fellow citizens. This view is epitomised by the lines of William Blake: "A robin redbreast in a cage puts all heaven in a rage; a dog starved at his master's gate predicts the ruin of the state".

The feeling of guilt is cousin to that of fear which forms the third major motive for our concern. Many people are fearful of retribution should they "do unto animals that which they would not have done to themselves".

The modern attitude to human welfare has, of course, always been a mixture of these motives. Further, the current tendency to exaggerate all aspects of human activity has made welfare something of a religion in itself, rather than part of a wider spiritual undertaking. Thus, we encounter priests and pastors who are, themselves, unsure of whether or not animals have souls and cannot, therefore, be expected to advise we lesser mortals on the subject. How can we decide on these matters when we have little basis for our own conclusions and "Like the Indian, in another life, expect our dog, our bottle and our wife".

The veterinary concern for animal welfare has no less a basis than pragmatism, guilt and fear. It is none the less proper for this; nor indeed, would failure be less improper in ourselves than in others, but rather more so. There are those who hold the view, as does the present writer, that the most important aspect of human attitude to animals—and to children or matters of race, religion and human behaviour—reflects more on the individual's qualities and character than on an absolute criteria of right and wrong, good or evil. No-one knows, for sure, what is good and evil, right or wrong, because they are, surely, relative values and changing determinants of human thought and, to some extent, mirror images of the other. The killing of an animal for pleasure must be put in a different light to that of killing for necessity—however tenuous the necessity may be. Deliberate or inadvertent ill-treatment of an animal is a pastime that must be condemned depending on the motives of the perpetrator. But if the motives are justified, such as where ill-treatment is a consequence of defence from attack, the spread of disease, the benefit of human beings or fellow creatures, the case rests on a definition of ill-treatment. And this, in turn, brings us to the impossible position of judgement in these matters, because what constitutes ill-treatment cannot be defined objectively. And as soon as it is defined subjectively the three motives for the concern of welfare are bound to operate to a greater or lesser degree.

Spectator sports, of course, by their very nature, come under close scrutiny by the public conscience, that amalgam of pragmatism, guilt and fear. I received, recently, a letter from a colleague telling me that a client of his had been concerned at what had taken place on the racecourse at Newmarket when the 311th running of the Town Plate occurred this year. The scene, to quote my correspondent, was more reminiscent of a battle field than of a competitive sporting event. A number of horses finished dead, injured or exhausted; and many riders in a similar, or near similar, state. Protests, and these were numerous, have met with a sympathetic response from the Jockey Club as to the conduct of the race in future, to avoid similar sufferings by horses, riders and spectators. However, one suggestion, which would need careful analysis by our profession, is that competitors should be required to produce a veterinary certificate stating that their horse was in a fit condition to compete over three and three quarter miles, carrying 12 stone under racing conditions. I do not know if there is any clinician who would be prepared to make such a pronouncement, until he had seen the horse compete under similar conditions, when it would, presumably, be too late to prevent the event.

Washington, DC 20003

Dear Mr. Bolstad,

Attached please find a summary table and notes resulting from expert panel discussions on September 24, 2015, exploring several alternative methods for wild horse spaying. In addition to veterinary and equine experts, several USGS, BLM, USDA-APHIS, and Colorado State University staff also observed and contributed to discussions.

The materials reflect professional opinions about the current state of understanding of four spay methods currently used on domestic horses, as represented and discussed by panel members during and after the day-long meeting. These materials do not provide BLM with a recommendation, but hopefully provide useful information for BLM to consider.

Sincerely,

Zack Bowen

Assessment of spay techniques for mares in field conditions

Panel meeting held at USGS Fort Collins Science Center

September 24, 2015

Summary of panel expert responses on four potential spay methods

	Colpotomy	**Ventral midline**	**Flank incision**	**Flank laparoscopy**
Facilities needed	Squeeze chute with a kick panel and access to the perineum.	Squeeze chute, table fitted on a forklift.	Squeeze chute (may require access to both sides).	Squeeze chute (may require access to both sides), sling.
Equipment needed	Ecraseur, scalpel or bistury, blunt scissors, gauze sponges tied with umbilical tape.	Complete surgical pack, surgical drapes, gauze sponges.	Complete surgical pack, surgical drapes, gauze sponges.	Laparoscope, CO_2 for insufflation, surgical pack, surgical drapes, gauze sponges.
Equipment preparation	Ecraseur autoclaved or cold-sterilized in ortho-phthalaldehyde (OPA/28) >10 minutes then rinsed in sterile water, or use chlorhexidine for sterilization.	Autoclave or cold-sterilize instruments.	Autoclave or cold-sterilize instruments.	Prepare laparoscopic equipment – cleaned and cold-sterilized.
Sedation	IV injection to the jugular of xylazine + butorphanol + detomadine.	Horses are placed in dorsal recumbency following an induction dose of xylazine/ butophenol/diazepam and ketamine.	Local lidocaine infiltration of flank and IV butorphanol.	IV jugular catheter continuous sedation drip - 20 mg detomidine in 1 liter fluid for standing sedation.
Anesthetic /analgesic protocol	Horses remain standing under tranquilization: butorphanol + xylazine or detomidine . Add low dose ketamine as needed.	Anesthesia may be maintained by IV administration of triple drip (IV-ketamine, xylazine and guaifenesin 5%) or using inhalant anesthesia.	Horses remain standing under tranquilization: butorphanol + xylazine or detomidine. Injection of lidocaine in line or L-block (~100-200 ml) at incision site.	Horses remain standing under tranquilization: butorphanol + xylazine or detomidine. Epidural for analgesia of the reproductive tract, local anesthesia at portal sites.
Procedure	Administer antibiotic (Excede - ceftiofur) that lasts for 4	Administer antibiotic (Excede - ceftiofur) that lasts for 4	Administer antibiotic (Excede - ceftiofur) that lasts for 4	Administer antibiotic (Excede - ceftiofur) that lasts for 4

	Colpotomy	Ventral midline	Flank incision	Flank laparoscopy
	days. Wrap tail and tie up. Evacuate rectum/bowel, prep perineum. Make 1 cm incision in vaginal fornix. Expand incision via blunt dissection. Locate ovaries. Sterile 4x4 gauze soaked with 30 ml 2% lidocaine compressed over ovarian pedicle 3-5 minutes or lidocaine injected into pedicle. Remove ovaries via ecraseur. Repeat for other ovary through same incision.	days (or given 40 ml procaine penicillin and 10 ml flunixin meglumine post surgery). Surgical area is clipped and prepped with chlorhexidine scrub followed by chlorhexidine solution swabs. Incision into peritoneum made on ventral midline. Ovaries exteriorized through ventral midline incision. An emasculator is applied to the ovarian pedicle. #6 MSA used to ligate the ovarian stump proximal to the emasculator. The emasculator is removed and the ligated stump allowed to retract into the abdomen. Closure is accomplished in three layers, the outermost being a subcuticular layer using #6 MSA absorbable.	days. Surgical area is clipped and prepped with chlorhexidine scrub followed by chlorhexidine solution swabs. Line or L-block injections are administered. Wait until block has effect, then single incision in left flank through skin and fascia followed by blunt dissection into the peritoneum. 9-inch burdizzo (or emasculator) for removal of ovaries. Closure of the underlying layers of muscle and fascia such that only the skin requires suturing. Very bottom of the skin suture line is left open to prevent seroma formation.	days. Approach both flanks: surgical area is clipped and prepped with chlorhexidine scrub followed by chlorhexidine solution swabs. Make incision at flank. Insert cannula for instruments. Insufflate with CO_2. Lidocaine injected to ovary and pedicle. Ovary is removed through incision; incision may have to be enlarged to remove ovary. Suture incision. Repeat on other side.
Incision	5 cm in anterior vagina.	9-15 cm incision made just cranial to the udder.	10-15 cm in flank (on one or both sides).	One 1 cm incision and one 6-10 cm incision in the left flank, and three 1 cm incisions on the right side.
Standing or recumbent surgery?	Standing	Recumbent	Standing	Standing
Surgery time per	15-20 minutes	20-30 minutes	45 minutes	40-60 minutes

	Colpotomy	Ventral midline	Flank incision	Flank laparoscopy
horse				
Complications	1-2% seen within 2 days.	Infection of open wound; potential for evisceration; potential for injury upon recovering from anesthesia.	5% incisional complications under sterile conditions (more likely 10-20% under field conditions).	1-2% incisional complications (in sterile environment), 10% subcutaneous edema; puncturing a bowel; dropping ovaries in abdomen.
Recovery time (before release)	3 days	2-3 weeks	2-4 weeks	1-2 weeks
Contra-indications	Uterine infection/pyometra. Enlarged (>6 cm) ovary; pelvic or ovarian abnormalities. Heavy late gestation may prevent access to ovaries. Surgery may not be possible if the mare cannot be sufficiently sedated.	Very dirty animal; old/multiparous; any animal that is contraindicated for general anesthesia. Contraindicated in later term gestation due to risk of initiating labor and abdominal wall rupture during parturition. Pregnant mares in surgery have a 3x greater risk of pregnancy loss with general anesthesia.	Very dirty animal; any animal that is contraindicated for general anesthesia. Pregnant mares in surgery have a 3x greater risk of pregnancy loss with general anesthesia.	Dependent on technology; abnormal ovary.
Effect on pregnant/lactating mares	Late gestation may challenge access to ovaries. Pregnancy no issue following first ±70 days. No foal abandonment issues. No issues with lactation.	Late gestation may be challenging. May affect nursing (pain when the foal tries to nurse).	Unknown. May affect nursing (pain when the foal tries to nurse).	Unknown, but likely easily done.
Effect of breeding post-surgery	Vaginal incision usually healed by 7-10 days post-	Breeding may cause injury prior to recovery.	Breeding may cause injury to the incision line.	Breeding may cause injury to the incision line.

	Colpotomy	Ventral midline	Flank incision	Flank laparoscopy
	surgery. If open or <100 days pregnant administer long acting progesterone which should suppress receptivity/save pregnancy.			
Operator safety	Strapping the back of the mare helps prevent kicking, kickboard and tail tied dorsally aids operator safety. Short time with scalpel.	Animal fully anesthetized.	Operator protected due to small window of access on side of animal. Longer time with scalpel.	Operator protected when coming from the flank, but injuries can occur due to equipment and two people in a restricted space.
Cost per horse	$250-$300[1] Long-acting progesterone ($7/mare)	$350[2] includes all drugs and supplies. Plus long-acting progesterone ($7/mare).	$350[2] Includes all drugs and supplies. Plus long-acting progesterone ($7/mare).	$450-$500[3] Long-acting progesterone ($7/mare).
Pro of method	Fast healing and recovery, quick surgery, can be done on pregnant mares.	Low risk to operator, common surgery for companion animals.	Low risk to operator, common surgery.	Direct visualization, low morbidity, good public opinion.
Con of method[4]	Higher risk to operator, need for trained surgeons.	Risk of evisceration, risk of incision infection.	Risk of incision infection and pain.	Most expensive and time-consuming approach.

Notes:

[1] Colpotomy cost per mare: $100-1500 initial equipment cost (chain ecraseur Jorgensen J-37E $450 buy 2 or 3, replacement chain MidWest 350.01254.2 J37ED1 $95). Then $80-100/mare: OPA/28 4 gal $99.56 (estimate 50-80 mares: $2/mare), suture 2-0 monocryl 36/box $205 ($6/mare), #10 or #21 scalpel blade 100/$25.52 ($3/mare), Lidocaine 100ml $8 ($4/mare), Xylazine $1/100 mg ($4/mare), Butorphanol 10mg/ml 50 ml $250 ($5/mare), Detomadine $16/mare, Ceftiofur - excede 15 ml $30/mare. Once the ecraseur and scalpels have been purchased, the expense via colpotomy for each mare is the drugs, the lidocaine and gauze for the pedicles, and the sterilizing of the ecraseur.

[2] Ventral midline and flank incision – there will be a cost of drapes, gowns, sutures, etc., as for all abdominal surgeries, and a cost for the surgical equipment. Drug and other equipment cost will be as in [1].

[3] Laparoscopy equipment costs: $25,000 for camera, light core, light source, monitor, Thorston telepack, $5,000 – insufflator, $3,000 – microscope, $750 x 6 for hand instruments (need two sets): $40,000 total new, or could buy used. Likely need to replace 5 hand instruments per 100 mares. Drug and other equipment cost will be as in [1].

[4] It should be noted that all surgeries are associated with a risk of death. There are no published data available to assess the mortality risk of any spay surgery in wild horses, although preliminary data on domestic and wild equids were discussed by the panel.

Assessment of spay techniques for mares in field conditions

Panel meeting held at USGS Fort Collins Science Center
September 24, 2015

Transcript of Comments

Questions or topics are in **bold**.
The speaker is in *italics*. If the person introducing the topic made the comment it is indented with a bullet. If the speaker is not known the comment is indented with a hyphen. All attendees and invitees have been given the opportunity to edit this document. As these are notes taken from a discussion, what is written here may not capture the exact intended meaning of a given statement.

Attendees

In person: Zach Bowen (USGS), Jason Bruemmer (CSU), Doug Eckery (USDA/APHIS), Paul Griffin (BLM), Al Kane (USDA/APHIS), Sarah King (CSU), Joanna Ruffino (USGS), Kate Schoenecker (USGS).
By WebEx/Phone: Cheryl Asa (St. Louis Zoo), Gail Collins (NPS), Robert Cope, Jay D'Ewart (BLM), Bryan Fuell (BLM), Dean Hendrickson (CSU), Katrin Hinrichs (Texas A&M), Sue McDonnell (U. Penn.), Leon Pielstick (DVM), Patricia Sertich (U. Penn.), Mark Stetter (CSU), Regina Turner (U. Penn.), Julie Weikel (DVM).
Information provided after the panel: Paul Zancanella (DVM)

Introduction

Paul Griffin

- Purpose of the meeting is to discuss different procedures for spaying wild horse mares.
- We will discuss pros and cons of the various methods that could potentially be used for spaying wild horse mares.
- This is not a definitive decision making meeting for BLM, but to get the opinions of experts.

Background of study to be conducted by USGS/CSU

Sarah King

- Aim of the study is to look at the short-term impact of spaying on health and behavior of individual mares, specifically any effects on band fidelity, spatial ecology and population demography.
- Location: White Mountain HMA, Wyoming.
- We have proposed to spay 60% of adult mares (adult mares are 3 years old and older), which will probably be 36-48 mares, depending on the age structure, leaving 24-32 untreated controls plus juveniles and foals.

- We will collect 1 year of pre-treatment data, and then 3 years of post-treatment data.

Facilities at Rock Springs BLM Adoption Facility

Al Kane:

- It's a typical BLM facility.
- Two hydraulic squeeze chutes. Most facilities do not have a split tailgate. At Rock Springs, the door would need to be re-fitted to have a split tailgate that would allow access to perform a colpotomy. It's an open question about whether BLM would have the funding to get a new tailgate (that is split).
- Squeeze chutes give access to the left side and hindquarters of the animal. They are - padded and compress the animal front to back and side to side.
- For recumbent surgery the mare can be rolled out of the chute onto the ground; no access to a table.
- No hospital and no indoor facility.
- Transportation to and from the HMA: gooseneck, stock type trailer, or semi-trailers.

Zack Bowen:

- We will compile notes and comments and put them in a briefing paper. This will not be published. It will be a statement to BLM compiling information, not making a recommendation.
- Information will be compiled based on considerations that will be asked of each technique.

Kane: Today we will discuss some considerations for what technique may be most appropriate for this study, but another technique may be more appropriate in the future for spaying on a wider scale across HMAs. But it may be the same.

King: The method chosen by the BLM for this study should be the same as what is used in the future elsewhere, as this will have been the method we gathered data on.

Discussion of Colpotomy - *Leon Pielstick*

History:

- Leon is a veterinarian who has worked with the BLM since 1975, and has also been involved with the management of horses at Sheldon-Hart. At Sheldon he spayed horses which had been placed on a private pasture for the trial.
- Spayed mares in the field successfully: Out of 34 mares spayed, 31 were open, 3 were pregnant and successfully foaled. At Sheldon they used spaying as a management tool – they vasectomized males and spayed females that were considered unadoptable, then turned them back out to the range. The majority of such spayed mares were pregnant.
- He has spayed 188 mares by colpotomy, including 16 spayed at a wild horse sanctuary in California, 16 spayed as part of a PZP safety study in Oregon.

- Out of the 188 mares there were 2 fatalities: one bled to death internally due to a clotting abnormality, and one got sick, aborted her foal and died (anecdotal evidence indicated that she had a peritoneal infection). We can expect a 1-2% complication rate with colpotomy. For any given choice of spay method, the BLM must be prepared to accept some level of loss.
- 70-75% of mares are likely to be pregnant in late summer. Pregnant mares can still be sterilized by colpotomy because of the way the foal drops in the uterus: the ovaries are still at the top of the uterus so can be reached. At 7-8 months pregnant it gets harder to move the intestines to reach the ovaries, so it is more difficult to keep the intestine out of the ecraseur tool. The only mare that had an abortion was the mare that died.
- To do the surgery, give heavy sedation/analgesia (butorphenol + xylazine or detomidine + Dormosedan) and heavy analgesics (banamine + butorphenol); the surgery is performed with the mares standing. Banamine was added to eliminate mild post surgical colic which had occurred in a few of the mares the first year in which the procedures were done.
- Mares held off feed for 24 hours before surgery seemed to have good recovery after. Holding off feed means that fecal balls are reduced, which can resemble ovaries on palpation and thus take time to sort out, and reduces abdominal fill. Depending on the horse there was a little colic within the first few hours post surgery until Banamine was added to the procedure. Mares generally walked out of the chute and started to eat, some would raise their tail and act as if they were defecating, however in most you could not notice signs of discomfort.
- There was no squeeze chute at Sheldon, but the mares could be held at the back of the chute where there was an access window. Some mares needed additional sedation as they could not be squeezed. It should be possible to make any facility functional for this surgery.

Facilities:

- Needs a kick panel and an access window, so that there is access to the perineal area. Use a strap above the rump, to help prevent jumping and kicking. Most facilities can be made functional. At the BLM Burns facility, for example, there is enough room to slide in a 3 foot tall plywood kick panel.

Behavior:

- In the first group of 33 spayed mares with 10 intact mares and 2 stallions (on private land) – the group all stayed together as a herd.
- In another situation two groups of 8 spayed mares formed their own bachelorette band. They were new to the facility.
- In Sheldon it is assumed that they returned to their band.

Recovery time:

- The only complications were seen within two days of surgery. After 2 days there were no visual problems so they could be released to the range.

- It is typically recommended in domestic mares that they not be ridden for a month, but they seem okay after 2 days.
- The incision in the anterior vagina is not sutured; this heals rapidly (within days, cannot be identified easily on speculum examination). Evisceration through the vaginal incision is often brought up as a possible complication of colpotomy, but none of the panel participants had had this occur nor had heard of it actually occurring. In addition, being held off feed would reduce the chance of evisceration.
- Being held off of feed before-hand is important according to Pielstick, although others said it was less necessary.

Gail Collins - At Sheldon they had the opportunity to recapture spayed mares that were released (3yr, 5yr, 6yr later) to monitor progress.

- They were given a dose of antibiotic (Excede -- ceftiofur) that lasts for 4 days within the mare (single injection).

Procedure:

- Cold sterilize ecraseur. Give antibiotic.
- Wrap tail and tie up for procedure.
- Evacuate bowel, surgically scrub peritoneum and flush out vagina. Clean vagina with iodine. Others perform procedure without vaginal flush (vagina should be essentially sterile).
- Put on sterile sleeves, introduced hand into vagina, and make the incision in the anterior vagina.
- Mares have no nerve receptors in that area, so they only feel pressure/stretching. They show no outward sign of discomfort. Mares feel the pull on and compression of the ovarian pedicle, but lidocaine administered to the pedicle to minimizes this. This analgesic lasts a couple / few hours. The pain afterwards is similar to that of castration.
- Timeline: 15 minutes for the whole procedure. Speed is often necessary due to volume of horses. Can do 30-35 horses a day as it is not physically taxing.
- Controlling the level of dust is very important, but otherwise it is possible to keep the area 'field sterile'.
- Can make a portable chute for this procedure out of a hydraulic cattle chute; this would have an adequate tail gate.
- Mares walk out of the surgery.

Comments:

Julie Weikel served as an observer for Leon's procedure at Sheldon; wrote a review:

- Some mares would walk out from surgery and immediately want to eat (hunger pain worse than spay pain due to keeping them off food).
- Some (a few individuals) showed minor signs of colic for about a half hour, such as getting up and down repeatedly. These were collected so that they could be watched more closely for up to an hour, then turned out to join a bigger group with feed and

water. For these horses they did not use lidocaine, which might alleviate the colic symptoms. Leon now uses liodocaine in every spay.

Katrin Hinrichs: **Did you give any antibiotics before the procedure?**

- Antibiotics are given after sedation, so not as long before surgery as ideal. There isn't a large opportunity to give it long before surgery due to the circumstances of these being wild horses.

How is the Lidocaine injected in to the pedicle?

- Via needle, an assistant pumps the drug, but the surgeon guides the needle.
- Dr. Pielstick is trying to modify the ecraseur to also hold a needle, thereby reducing the overall risk of contamination (and needle stick); having the needle on the ecraseur would mean one less trip in and out of the abdomen.

Are the mares in pain after the drugs wear off? Are they observed at night?

Hinrichs: has seen mares in pain at night after the surgery; she now gives butorphanol for 24 h after surgery, or morphine + detomidine epidural at the time of surgery.

Pielstick: They are observed for several hours after. They seem fairly comfortable. Pain is at an acceptable level; the banamine helps.

- Domestic mares are given banamine and sent home.
- They seem more comfortable than castrated stallions.

Weikel: I walked pens every morning and evening at the gather observing behavior. Mares were mostly involved in social status behaviors.

Pielstick: Finished surgery at 4pm on a good day, so not a lot of light for observations after surgeries.

Regina Turner: **What is the effect of operator experience?**

- This is a practical technique. Leon taught 9 vets in Arizona when spaying 5 donkeys. Any vet who generally works with equine reproduction can pick it up, however there is a learning curve. On one donkey they had trouble getting the left ovary out, after they finally succeeded the donkey bled to death. They did a flank incision on two donkeys and this seemed better on that species.

Are there enough trained people?

- Plenty of vets would be interested in learning the technique. If there is a complication it can be used as a learning experience to avoid future complications. There were complications with the donkeys as multiple people were learning how to do it. The chance of complications increases with the number of times you go in and out of the animal.

Cheryl Asa: **Could we have more follow up on the AZ procedures?**

- Concerns about the Arizona project include the fact that one died, one lost a 50-70 day old fetus, and others had post-operative infections.

Pielstick: The burro that died had a left ovary with a membrane around it; there was no post mortem exam to discern exact cause of death. If a female has an unusual ovary it would be best to abort surgery and not proceed.

It seems as though the training contributed significantly to the mortality there?

- If there are unusual situations then generally complications arise, and this is used as a learning curve to create a better procedure.
- It is also worth noting that the number of learning surgeons entering the body cavity of those burros could have contributed to the one in five mortality rate for those burros. Dr. Asa noted that one of the major complications could have been the training itself.

Kane: **What are the contra-indications of this technique? Does the condition of the horse affect the procedure?**

- Generally body condition will affect the choice made to do the procedure. Best to pass on very old mares or mares in poor condition.
- Late gestation will increase the complication rate, but pregnancy will not be an issue in the first or second trimester.
- Surgeons should also pass on mares with pelvic abnormalities.
- 1-2% of mares could not be sedated heavily enough to do the procedure. 1cc of ketamine would help. If a mare fails to sedate the issue is that she moves, so the procedure is not done.

Of the big group of mares that you spayed, what percentage were pregnant? Which were checked before-hand?

- Of the first 33 mares that had the procedure, 3 were pregnant (about 60-70 days). All 3 foaled.
- The 16 spayed in CA were all open.
- At Sheldon 70-80% were pregnant - up to 7 or 8½ months gestation. Ovaries were easy to reach, but it was generally a little harder with the foal in the uterus.

Did it affect pregnant or lactating mares to keep them off feed?

Pielstick: They were only held off feed for 24 hours, and were given water. Mares were released with their foals. There were no abandonment issues.

Hinrichs: does not hold off of food and has not had an issue.

Pielstick: feels holding off food is important; the less abdominal fill, the better.

Hinrichs: **How long do you take to close the ecraseur?**

Pielstick: A few seconds.

Griffin: **Could we release into the wild and worry about potential breeding?**

Hinrichs: The result of ecraseur is a very clean pedicle, as she has had the opportunity to observe via flank incision during removal of ovaries with the ecraseur. Additionally, after 2 or 3 days you can barely see the incision in the vagina, but if she is mated at that time it could open up the incision.

- There is a chance they could be in heat, but if the procedure is in fall many will be pregnant.

- There is a concern that, if they are bred shortly after the procedure, the vaginal incision could be opened by the stallion's penis. This could result in peritonitis and death of the mare.

Patricia Sertich: Not necessary to hold off feed. Instead rely on careful palpation of the uterus and ovary. 32 years experience doing ovariectomy by colpotomy. The initial incision (<1cm) is made in the vaginal fornix with a no.10 scalpel and the incision is enlarged by blunt dissection. This method separates rather than transects the muscle fibers so the incision decreases in length when the vaginal muscles contract after the tranquilization wanes post-surgery. Three days post-op the incision edges are adhered, and healed after 7-10 days. If the mare is not pregnant or less than 60-80 days pregnant she will likely tolerate copulation by a stallion in 3-7 days due to the decrease in ovarian progesterone.

Hinrichs: They could be given an injection of a long-lasting progesterone (e.g. Altrenogest) to stop the mare tolerating stallion advances.

Asa: Estrus behavior is seen in pregnant mares, but in our study they did not not allow copulation.

Pielstick: could do a study to monitor how often mares show heat after spaying.

Sue McDonnell: Spayed mares can be receptive all year round. Typically can not even put them with geldings as they would be mounted. If given the opportunity a spayed mare would tolerate the sexual advance of an amorous gelding. If over 100 days pregnant at the time of ovariectomy, and don't immediately lose the pregnancy, the feto-placental unit has taken over from the ovary for progesterone to support the pregnancy, and without the ovary will likely suppress attractivity and receptivity.

Kane: **What are the long-term complications of spaying? What is the incidence of pyometras in spayed mares?**

Gail Collins: At Sheldon 85% of mares that had been spayed and released (plus 30 mares not spayed) were recaptured. The survival rate of spayed and non-spayed mares was not different.

Hinrichs: Breeding is not a problem if the incision is elsewhere than the vagina.

- There may be a long-term risk of vaginitis and pyometra in spayed mares if bred repeatedly after spaying. There is risk of penetration into the abdomen and peritonitis if mares are allowed to breed before the vaginal incision has healed.

Hinrichs: This is unlikely as the cervix will be open due to lack of progesterone (no ovaries).

Griffin: **How long should we keep mares in captivity?**

Collins: At Sheldon they kept them in for 7-8 days before release.

Hinrichs: Has just visited a lab that does a lumbosacral epidural on mares for oocyte recovery. This would eliminate the need for lidocaine and make sure the mare does not move during the procedure. May not be feasible in wild mares. The lumbosacral was given while the perineum was being prepared; done at the level of the tuber coxae. Lab she visited has used this on client mares over 300 times successfully.

Pielstick: It may be faster to just block the ovarian pedicle.

Discussion of ventral midline and flank incision approach - *Julie Weikel*

History

- Julie has spayed about 100,000 cows by either flank or vaginal approach. The vast majority of these were spayed by the vaginal approach, however several hundred were spayed through the flank at all stages of pregnancy. These experiences are the ones that inform our discussion about spaying mares as there are many similarities in the issues faced and potential consequences. The adult cattle spays were all performed as part of federal Brucellosis eradication efforts. Under the Brucellosis control program neither sexually intact nor pregnant animals could leave a quarantined premises, hence the need for both spays and C-sections, frequently in the same individual animals. Rarely were the conditions under which these surgeries occurred ideal in any way; cleanliness, weather, adequate manpower, etc. In other words, true field conditions. While Julie always tried to obtain follow-up information about complications and survival, she did not always get that feedback. Some of the problems in cattle might inform the discussion.
- In cows you cannot reach the ovary through the vagina when they are pregnant, so had to go through the flank.
- All the mares (domestic) Julie spayed were via a single flank approach, probably less than a dozen. They were all decades ago and were for either granulosa cell tumor removal or attempts to control "nymphomania." All were done in horses used to being handled and in a clinical environment.
- Entry for flank spays utilized a skin and fascia incision followed by blunt dissection that results in a "closure" of the underlying layers of muscle and fascia such that only the skin requires suturing. Only the very bottom of that skin suture line is left open. Julie came to this procedure as a result of dealing with seromas as a not uncommon sequence in fully closed suture lines. Seromas are not a serious post surgical complication, but in field situations where any secondary handling poses additional risk to the animal, they should be avoided if possible.
- In mares always used a 9 inch burdizzo rather than an ecraseur when doing flank incisions. Has never had a hemorrhage issue with castration using the burdizzo.
- P. 869 in Loesch and Rodgerson (2003) article is very thorough in regards to complications from any non-colpotomy approach in a horse.
- Always better to do surgery with a horse standing if possible – want to avoid lying horses down. Surgical vasectomies are done recumbent.
- Surgical recovery in a wild horse is already an extraordinary event (i.e., presenting unusual circumstances).

Conditions:

- Dust control is crucial (not completely sterile by any means).
- Heifer corrals mirror field conditions.
- Any surgery poses an issue for infection at the incision site.

Training:

- Julie has taught numerous vets to spay heifers. Only a small percentage are still spaying. All found it to be quite difficult. Adopting colpotomy for wild mares means that we need to find people who have gone through the steep learning curve. Some people can develop a good feel to correctly assess what tissue you have hold of, but it takes experience to learn.
- In the west, many dude ranches do not like cycling mares. Julie works with a veterinarian who spays these mares. Other vets with this experience are a potential for pool of people to choose from for the colpotomy method.
- While Julie has usually required 100 heifers to "train" a veterinarian to spay heifers, 100 mares may not be necessary to train an already accomplished equine surgeon to perform colpotomies. Training will vary with the individuals involved and hopefully could be accomplished with many fewer animals, maybe 5-10, with time to rest between surgeries for reflection during training.

Comments:

Hinrichs: Feels there is not such a problem with training veterinarians for equine ovariectomies via colpotomy. Did ovariectomies by colpotomy for PhD work – everyone wanted to learn the technique. Reproduction vets are best because they can tell if the ovary is covered by omentum, and recognize the anatomy better via palpation than surgeons. They are more familiar with the feel of it. Katrin has trained many veterinarians on ovariectomy via colpotomy, and they have been successful. They have conducted colpotomy on 22-30 year old mares with no complications. Reproductive specialists are used to palpating mares, so the colpotomy method is not difficult to teach.

Weikel: The biggest mistake is that trainees are too eager to jump right in and because the initial entrance into the abdomen is extremely important this causes an issue. During autopsies of spayed heifers the vaginal wall penetration site was difficult to find. This was observed in heifers only because she has never lost a mare.

Griffin: **Is there a minimum number of mares to use to teach people how to do the procedure?**

Hinrichs: 3-5 colpotomies should be done under supervision.

Weikel: People who were good had it after 1-2 animals. There are others who still wouldn't get it after 100. You need people with experience or competence.

- Dust control is critical – spray pens down every day, and re-spray during the day. In her opinion, field conditions make colpotomy an attractive option.

Kane: **Is there one incision or both flanks?**

- Single incision (left flank) and does the left ovary first. Dr. Weickel uses the burdizzo to access the second ovary, carrying the tool though the abdomen.

Chemical immobilization?

- Lidocaine and adequate sedation (butorphenol). Some mares respond differently – can't settle even when sedated. These are generally released without surgery.
- Sedation is an important variable.

Issues with flank incisions?

- It's an open wound. An external wound can become an abscess.

Recovery time? Or effects on pregnant mare?

- Cannot speak first hand on the flank approach in pregnant mares.
- In heifers Weikel would attempt vaginally or go in via flank. She would C-section (after 120 days pregnancy) therefore could see the ovary and proceed.

Turner: It will be harder to find people who are good at colpotomies. Some people prefer flank incisions, and more people are trained to do it. However flank incisions can take longer to heal and be more painful.

Weickel concurred that colpotomy appears less painful.

Kane: **Can anyone comment on the access to the ovaries on pregnant mares via flank incisions?**

[No response from the panel]

Kane: **Recovery time on flank incision?**

Weikel: There is a prolonged recovery time (2-3 weeks) due to the risk of abscesses developing after surgery.

Asa: Following up with data from the burro project: 2 were spayed via flank incision. These got infected and opened up within a week. They took a month to heal. These animals were closely monitored.

Turner: You will likely be able to find more veterinarians who are trained in and comfortable with flank incisions for ovariectomy. However, there are many complications in flank incisions even under sterile conditions. Most of these are related to healing of the incision line and discomfort. On the other hand, it will be hard to find people who are good at colpotomy. When untrained people perform colpotomies there is in an increased risk that things will go wrong and sometimes things can go very wrong.

Weikel: We need to be conscious of trained personnel who are good at colpotomy to teach others to do this procedure so they can take over if there are complications.

Hinrichs: has not had issues training people, however, she is very detailed in her training methods. She goes through every complication she has experienced with each new trainee. Reiterated that she prefers reproductive vets over surgeons.

Kane: **Safety of the people involved during the surgery?**

- Colpotomy – strapping the back of the mare helped stopped the mare from kicking, plus there is a kickboard and the tail is tied up.
- Flank incision – operator can be more protected. Small window of access. Weikel does not believe that this outweighs the consideration of the colpotomy.
- Hinrichs noted that the time with the scalpel in colpotomy is only a couple of seconds. This time is longer for flank incision, which means more opportunity for fractiousness and infection.

Ventral midline incision approach: *Jay D'Ewart*

Procedure

- 8 mares were spayed using the ventral midline approach at Rock Springs, WY. All survived. It was not a blind procedure. Done under anesthetic with the surgery similar to a dog or cat. Given three-layer sutures. After surgery the mare got up and wandered to the recovery pen. The mares were watched for 2-3 weeks at Rock Springs and then sent to long-term holding facilities.

Comments:

Kane: **Were the mares pregnant? How long after were they turned out?**

- Unsure if any mares were pregnant, but it is unlikely as they had been in holding for some time prior to surgery.
- These mares were never released to the range (they are in long-term holding somewhere).

Griffin: **How would this affect pregnant mares?**

Hinrichs: It would be difficult to access ovaries via ventral midline in a pregnant mare.

Kane: **How would this affect lactating mares?**

D'Ewart: Might be able to select mares that are close to weaning.

Weikel: It is likely to be more of a problem if the mare is still sore. In heifers there is soreness due to the calf poking around to nurse. The relationship between dam and foal could be compromised. Edema could affect lactation. Flank incision might also make some mares resistant to nursing.

Griffin: **With the ventral midline procedure is there a potential for evisceration?**

Weickel: Yes, definitely. This is a primary possible complication of this procedure, and it is an awful outcome.

Hinrichs: what is the incision size?

D'Ewart: 5 inches

[Referred to Loesch and Rodgerson (2003): 25-35 cm]

Weikel: depends on the size of the ovary and size of the operator's hand.

Doug Eckery: close to the mammary gland, so may affect nursing.

- Evisceration is a horrific consequence so we want to be careful of a method in which evisceration is a complication, as in ventral midline.

Hinrichs: Although evisceration is said to be a risk of colpotomy, she has not known of any evisceration post-colpotomy.

[Neither had people at U. Penn.]

Sertich: Domestic horses that have had a ventral midline incision are usually restricted to stall rest for one month, and then only hand walked for the second month. These horses are kept with very limited activity. No data on mares that had free access to exercise.

D'Ewart: Had a successful experience in Wyoming. After anesthesia the horses are turned out in a holding pen where they don't get a lot of exercise. No eviscerations. The vet thinks it is a very teachable procedure.

King: We will be sending the briefing statement to Paul Zancanella who conducts and advocates for the ventral midline approach. He can add comments.

Ventral midline procedure - Paul Zancanella (written comment submitted after the panel)

- Mares are restrained in a padded chute and administered an induction dose of xylazine and ketamine. Upon induction an indwelling catheter was installed in the jugular vein. Anesthesia was maintained using intravenous administration of triple drip (IV-ketamine, zylazine and Guiafensin 5%) to effect. Horses are placed in dorsal recumbency. Surgical area is clipped, pre-surgical preparation was done with chlorhex scrub followed by chorhex solution swabs. Seven-inch incisions were made just cranial to the udder. Ovaries are exteriorized through the incision. A serra emasculator is applied to the ovarian stump. Number 6 MSA is used to ligate the ovarian stump proximal to the emasculator. The emasculator is removed and the ligated stump allowed to retract into the abdomen.
- Closure is accomplished in three layers. The outermost being a subcuticular layer using #6 MSA absorbable. The surgical time, induction to completion, is twenty to thirty minutes.
- Mares all received 40 ml procaine penicillin and 10 ml flunixin meglumine post surgery.
- Mares are standing within thirty minutes of surgery and eating within two hours of surgery.
- In conclusion, a ventral midline ovariectomy is a viable field surgical procedure for fertility control in mares. The surgery is accomplished relatively easily with less risk and expense than other fertility control methods.
- The ventral midline can be performed with little or no modifications to the existing facilities.
- Postoperative pain is much less than colpotomy and is easily managed with intraoperative IV flunixin meglumine.
- Operator and assistants safety is much better than standing procedures.
- Some concerns expressed for mares being anesthetized is exaggerated or naïve. Equine practitioners anesthetize thousands of horses with minimal problems.
- Ventral midline surgeries are accomplished routinely on horses without complications.
- Having performed both the colpotomy and ventral midline I much prefer the ventral midline approach.

Kane: We need sedation and anesthetic protocols for the three incision approaches.
Griffin: **Is there something additional about lying horses down that is an issue?**
Weikel: There is a lot of weight on the tissues if on its back, pressure on the aorta (cardiovascular effects), and recovery issues; these are mentioned in the review article [Loesch and Rodgerson (2003)]. When a domestic horse that trusts you is recovering you can keep them calm and help them. With wild horses this is not an option. The goal is to get away from them (and get them

away from people) as soon as possible. They can sometimes run and buck/get acrobatic; level ground is a must for recovery.
[*Hinrichs* and *Turner* agree with not laying horses down for surgery if at all possible.]
Hinrichs: We always do ovariectomy surgery standing. Injectable sedation for ventral midline seems risky, as compared to gas anesthesia. People are moving away from abdominal incisions in humans; for example in women they are doing hysterectomy etc. via colpotomy and this is associated with less pain and much faster recovery.
Weikel: There is potential for adhesions to the ovary, for example due to a history of inflammation. Those are problematic. Leon will not take such ovaries out of mares. Individuals with these inflammations are high risk - heifers walked around with the hump in their back even if they lived. Would be skeptical if there are adhesions.
King: **Is this similar to cryptorchid stallions?**

- If a mare has an ovary left she will still cycle, even if one ovary is infertile. Generally in cryptorchids they do not have adhesions, so not really comparable.

Kane: **What are contra-indications for flank or midline methods?**
Weickel: No external surgical incisions should be done on any mare that is very dirty. Any mare that is especially dirty we need to ask why is she laying down and rolling a lot. Will she be doing this post-surgical procedure? How dirty are the field conditions? At Sheldon, the corral where the surgeries took place was clean, and not used at all for many months per year.
Sertich: Would avoid ventral midline incisions in late gestation in mares (in last month before parturition) as they may go into labor. Some mares have delivered foals after midline surgery for colic, but they were watched carefully. The concern is that there may be a breakdown of the abdominal wall during delivery.
Kane: **Is there an age effect for these approaches?**
Sertich: No specific numbers, but as mares get older they are more at risk for abdominal wall rupture.
Turner: Older/multiparous mares have an increased risk under general anesthesia because they may be at increased risk for catastrophic fracture during the recovery process. Also, many physical conditions would preclude the use of general anesthesia and subsequent recovery (e.g. neurologic horses, horses with heart conditions, etc.) Any of these conditions would be contraindications for general anesthesia and therefore the ventral midline approach. Mares would need to have a full physical examination prior to anesthesia, which is unlikely in the field.
Sertich: Mares that lactate year round every year probably have lower bone density, so are more at risk of catastrophic fractures during recovery from general anesthesia. These risks are inherent to the recovery process following general anesthesia (not the method of surgery chosen). But since the ventral midline approach can only be done under general anesthesia, these potential complications would be unavoidable with ventral midline (vs. other procedures that could be done standing).

Weikel: The Sheldon mares (colpotomy) spayed were skewed towards older mares. The recovery was the same as the mares that did not have the procedure, but all of these mares were done standing and did not have general anesthesia.
Hinrichs: 8 mares 21-30 years old were given ovariectomies by (standing) colpotomy without complication.
Kate Schoenecker: **How does an ovariectomy affect the fetus?**
Hinrichs: [will be sending the research paper cited to Joanna] Mares ovariectomized earlier than 50 days – all lost their fetus. At 50-70 days about half lost their pregnancy. >140 days none lost their foal. In her own research, took ovariectomized mares off progesterone after 100 days of gestation and then had no problem.
Sertich: When mares get abdominal surgery of any kind they are also administered progesterone/progestin before and for a few weeks after surgery to prevent pregnancy loss. There is less risk of losing a foal with a colpotomy. General anesthesia for a ventral midline incision requires that the horse is off its feed, which means more muscle trauma and more stress.
Turner: Pregnant mares in surgery have a 3x greater risk of pregnancy loss with general anesthesia.
Griffin: **Due to colpotomy sometimes early stage pregnancy can be lost. Can we give them long term progesterone injection to save the pregnancy?**
Hinrichs: It could be possible to keep ovariectomized mares pregnant by injecting progesterone. At <50 days of gestation won't find evidence of fetal loss. Pregnancies of 50-70 days might be helped by a long-lasting progesterone shot. Pregnancies over 70 days are likely to be maintained even without exogenous progesterone.
Kane: **What product would you recommend?**
Hinrichs: Not sure on commercial availability of certain products. BET had a long-lasting progesterone and long-acting altrenogest that was available. (Checked subsequent to the panel: 30-day altrenogest injection still available).
Kane: **Potential for a feed through on mares that die due to this procedure in the wild?**
Hinrichs: Main issue is if an animal were to eat the area of the mare where the progesterone is injected, but progesterone is a natural hormone and the consumer would just receive an oral dose. (Note added later: Altrenogest does have the potential for feed-through).
Kane: If gestational stage is <50 days, we should consider accepting fetal loss. If stage is 50-70 days, one could consider injecting a drug to maintain the pregnancy.
Hinrichs: **Does anyone know what time in gestation an abortion is visible?**
Kane: It is very difficult to find aborted fetuses, even in a stall. Most that are found are close to term (size of a beagle). There are behavioral signs preceding abortion. We want to avoid abortions to the extent possible.

- Beagle size is 150 or more days (5-6 months) gestation.

Collins: We rarely found aborted fetuses in corrals. Only a few times did we find beagle size fetuses.

How often is the fetus reabsorbed?

Sertich: It is thought to be expelled/passed out through the cervix and not found, rather than resorbed.
Weikel: When it's hormonal abortion we are less likely to see discharge from the mare. When it is infection one sees a messier discharge.
Kane: Horses are corralled for testing purposes and held for 30-90 days. We vary rarely see secondary complications in mares that abort a fetus. The complications with abortion of foals are minimal. The mares do not show signs of illness, pyometra, or founder. The mares are generally farther along when we see complications, if any.
Hinrichs: In Argentina the polo industry is aborting hundreds of male foals, then within a few weeks transferring another embryo to the same mare with no ill effects.

Discussion of Laparoscopy: *Dean Hendrickson*

Procedure:

- Done a lot in horses at CSU. Performed in domestic horses with standing sedation. Typically approach both flanks. Can do it through one flank but this takes more time. Typically it takes 40 mins to remove both ovaries (doesn't include time for preparing/sterilizing horses for surgery, which brings the total to 50-60 minutes per animal).
- Equipment needed is a laparoscopic tower, light source and monitor, camera box, CO_2 canister, insufflator, and one standard surgery pack per animal (scalpel, blades, clamps, etc.).

Recovery time:

- Some are sent home the same day or some stay over night. There is minimal postoperative care.
- Has done the surgery in a field setting (laparoscopic vasectomy of elephants in Africa). Can keep the animals/instruments clean and sterile enough with cold sterilization.
- Standing sedation may not be possible in a wild horse for this surgery.
- The effect on the fetus if the hormones are not maintained (at less than 50 days gestation) is that the mares will generally abort. It is most likely that there is the same level of risk as for other procedures.

Comments:

Hinrichs: **What is the sterilization time for the instruments?**

- About 20 minutes to sterilize between animals (would work better with 2 sets of instruments to avoid wasting time).

Jason Bruemmer: **If you were to do it from only one side does it affect your time of completion?**

- Yes, it can take up to an hour standing sedated in a squeeze chute if surgery is from one side.

Sertich: When we do ovariectomies by laparoscopy they allow 1 to 1.5 hours, which includes scrubbing the flanks. They make incisions from both sides to get both ovaries.

Collins: **How is sedation maintained?**

- IV jugular catheter, continuous sedation drip. More consistent than with a bolus.
- Have done epidural (caudal) which also works well, but not sure this will work for wild mares.
- With this procedure in elephants they are under general anesthetic and hung in a sling from a crane so there is access to the flanks. Not sure if this is possible for horses.

What is the size of the incision?

- Ovaries are removed through the flank. Incision size is dependent on the size of the ovary (just enough to pop the ovary through), normally 4-10 cm.
- In 2% of cases there is incisional drainage, and in 10% there is subcutaneous emphysema from the CO_2 insufflation.

How are they managed post operatively?

- 1 dose of antibiotics pre-op and 3-5 days of NSAID post-op.
- Kept in a pen for 1 week, and then normal work after 2 weeks. But would not have a problem waking the mares up and sending them off.

Is it possible to use the laparoscope vaginally?

- Yes, there have been two reports using it to aid in colpotomy.

King: **Have you ever carried out this procedure on a pregnant mare?**

- No.

Hinrichs: **What type of epidural do you use?**

- Caudal epidural as it reduces movement. But there is no flexibility in that method of sedation as if you put in too much it's hard to keep them standing, and too little means they aren't sufficiently sedated.
- 40 µg/kg detomidine is used. Lidocaine would require too much volume to be used as an epidural.

Do you use lidocaine on the ovary?

- Yes – injected into the ovarian pedicle (15 ml local anesthetic injected to the pedicle).Give an epidural for analgesia of the reproductive tract, rather than the flank.

Kane: **Can you comment on the ventral approach?**

- It makes laparoscopy more difficult. When dorsal it is harder to get to the ovaries and find them. Ovaries present better when standing from the flank.
- In the small animal world they put the animal head down tail up and tip them from side to side. It might be possible to roll horses one side to the other to get to the ovaries.

Kane: **What are the general equipment costs?**

- $25,000 for camera, light core, light source, monitor, Thorston telepacs (sp.?)
- $5,000 - insufflator
- $3,000 - microscope

- $750 x 6 for hand instruments
- $40,000 total new, or could buy used.
- You would need two sets of instruments to be efficient, so that one set could be cold sterilizing while the other was in use.

Kane: **Contra-indications for this method?**

- You are very dependent upon technology – if something breaks and you don't have a duplicate then you need to stop. It takes time to get used to the approach and do it.
- Worst-case complications would be puncturing a bowel. Withholding feed tends to reduce this risk.
- It is possible to drop ovaries in the abdomen. There is no proof that this is an issue but could be.

Durability of equipment?

- Not a huge worry – machinery is not that delicate. The monitor is most delicate - if kicked it could break the screen.

What do you recommend for pre-op?

- 12 hours off feed but not critical. The more comfortable you are with the tech the less you need to worry about feed – 3 hours would be fine. Time off food possibly upsets them. Elephants were never held off feed and they have similar digestive tracts.

Hinrichs: **How long does it take to learn the procedure?**

- With 3 days and 5 or 6 mares you can get someone up to speed. Doing it regularly helps. Has learned how to teach it well. Ovaries in a standing mare are easy to access. It is not difficult to do an ovariectomy.

Kane: **Can you guess what would happen in a pregnant mare?**

- Pregnant mares present ovaries well if standing. It could be easily done.

Do you have any ideas about slinging them under anesthesia in a chute?

- Can use the same concept as hoisting horses up and out of ditches. You can use this to keep them into position.
- You could potentially have two teams working on either side of the abdomen and cut your time shorter.

Hinrichs: **What is the infection rate?**

- It's about 1/10 less when the instruments go in and out of the body cavity through a cannula, rather than flank laparotomy where they go repeatedly in and out through an incision. Instead of 5 in 100 you'll get 1 in 100.
- We don't see them commonly in open flank procedure.

Kane: **How safe is this procedure for the operator?**

- Coming from the flank you can avoid the feet, but he has still ended up with bruises and a broken toe.
- The difficulty is the amount of equipment and two people puts you a little more at risk than standing flank ecraseur, but slightly safer than a colpotomy.

How do you feel about training on a large scale?

- He feels good about training people fully. Colpotomy is rough because you cannot see what you are doing. One could use the laparoscope to train colpotomy.
- Won't walk away from someone until comfortable that they could do it.

Hinrichs: When training students on colpotomy, the student will find the ovary and place it in the loop of the ecraseur, then she will put her hand in and make sure it's an ovary before anything is cut.

Griffin: **Can you comment on the approximate cost the procedure will be per animal?**

- CSU charge is $1400 to do mare ovariectomy at the hospital (including technician time).
- Could do it in the field for $250/ horse for procedure alone (not including salaries).
- Did ovariectomies on dude ranch mares in Durango – 11 horses in 3 days. The real cost was $450-$500 per horse.

What is the cost per colpotomy and ventral midline?

Collins: Colpotomy was $250-$300 per horse at Sheldon NWR.

- Ventral midline is approximately $350/horse at Rock Springs, WY.

Fragility of the equipment? Is the jostling of the wild mares going to be an issue for the equipment?

- Wise choice is per 100 mares look to replace 5 instruments (this is the rate with people who are not fiscally responsible for the equipment).
- More likely to break hand instruments than the scope.
- Laparoscopy is the most expensive approach, but there is direct visualization, low morbidity, and better public opinion.

Schoenecker: **Do you cold sterilize?**

- Yes. Clean with soap and then water, rinse with sterile water.

What happens with dust?

- Blowing dust is less of a problem as the instruments are solid. Has been able to brush dust off during elephant procedures.

Sertich: **Infection issues or seromas?**

- One does get some seromas but no big problems with them. 1-2% incisional complications, but those rates are for mares in a clean and controlled environment. Opening and draining generally fixes this.
- No long-term negative or infection rates. In a field setting there may be a 2-3 x higher risk, but this is still small and corrects on its own.

D' Ewart: **Is there a difference in laparoscopy vs just through the flank?**

- You can see what you are doing with lap.
- You can ligate the pedicle with two ($10) ligatures to cut sharply, rather than putting the ecraseur through with a flank incision.
- Two ligating loops is faster than the radiofrequency "Ligasure".

- There is a radio frequency device for cauterizing the ligated tissue, but it is expensive and finicky, and is just one more piece of equipment to worry about that may halt surgeries.

Bruemmer: **Can you use umbilical clamps?**

- Seems like you could. Thicker pedicle in the horse than cattle.

D'Ewart: **What is the infection rate difference in flank than scope?**

- 5% incisional infection for flank.
- 2% with laparoscopy.

Hinrichs: **Is the opening for the ovary a straight incision? How is it closed?**

- Incision of 5-10 cm modified grid. Close fascia and skin in continuous pattern.

D'Ewart: **How do you manage pain?**

- A lot of the pain comes from the flank incision. It is helpful to anesthetize the pedicle (with carbocaine).
- Since laparoscopy incision is smaller than with the flank laparotomy method, it is mildly less painful but not a huge difference.

Behavioral estrus post spaying: *Cheryl Asa*

History

- 10 ovariectomized mares and 10 anovulatory mares were put with stallions and monitored for 15 days in January. The study was published in 1980.
- Of the 20 mares all showed at least one day of weak estrus. One mare showed full estrus all 15 days. Most had at least some mounting and were accepting of a stallion to full copulation.
- Most notable is that there was nothing cyclic (it was on and off day to day).
- Considering our various studies, only when a mare had elevated progesterone (e.g., diestrus, pregnancy) was there an absence of estrus and copulation. The adrenal cortex produces sex steroids. Estrus was not shown in mares with adrenal cortical hormone production was blocked with dexamethasone, suggesting that it is adrenal sex steroids that support estrus in mares that are ovariectomized and during the non-breeding season.
- It would be interesting to know whether this represents what mares would do in a naturalistic circumstance.

Comments:

Weikel: **What was the relationship between stallion and exposure? And relationship to spay?**

- Mares and stallions were kept separate and introduced (several mares and a stallion in a paddock) and allowed to interact freely.

Weikel: The increase in breeding activity may have been because the mares were new to the stallion. In Asa's study, the stallions were not with the mares except during the study.

Collins: Didn't monitor for sexual behavior at Sheldon but did analyze band association. Spayed mares maintained their band associations, and were in mixed groups. They were not found in bachelorette bands, or as solitary animals.

Is there a more natural setting?

Asa: Horses stay together year round (unlike most animals), so behavioral estrus may be a mechanism for the band to stay together outside of the breeding season.

Collins: Mares that were not coming into estrus were not driven off or kicked out the band.

Hinrichs: **In an intact band full of intact mares what portion of those mares would not be pregnant?**

Collins: 45-50% recruitment in Sheldon.

Asa: Reviewed horse literature for the NAS report. It looked like there was a trend where mares on BLM range were reproducing about every other year.

Kane: varies from HMA to HMA. 60-75% of mares are coming up pregnant based on fecal testing or foaling. There is 75-80% pregnancy rate based on fecal testing or foaling, observed at Teddy Roosevelt NP.

Collins: Most foal deaths were within the first 2 months of life.

Griffin: If a foal survives to fall, then typically BLM would consider it part of the population. "Recruitment" is survival to nearly a year old.

King: **Any other observations of behavioral differences in mares post ovariectomy?**

Sertich: Teaser mares (stimulus mares for semen collection) are ovarectomized. They are sexually receptive to stallion advances every day for the rest of their lives. Sometimes ovariectomized mares are administered estrogen to encourage proceptivity, but most of the time they are not. Ovariectomy to prepare a stimulus mare is common in the horse breeding industry for semen collection to be used for artificial insemination.

Griffin: The main reason we are asking USGS to conduct this study is because this behavior is not well known, so part of the purpose of this study is to discover that.

Griffin: **An injection of progesterone would create more time for the mare to heal by making her less receptive to being bred?**

Hinrichs: Yes. A long-acting progesterone given at a concentration of 1-2 ng/ml could suffice. They should reject the stallion for about 7-10 days.

Kane: **Any concern about exogenous progesterone affecting post-operative uterine infection rates?**

Hinrichs- There could be concern, but because the cervix may open shortly thereafter, when the progesterone level falls, this should be self-limiting. Some contamination could occur during the procedure, but because of antibiotics the likelihood of infection would be low.

Collins: **If you are doing the surgery when is the injection being administered?**

Collins: At Sheldon we held animals for a week, and restricted the number of times they handled the animals.

Hinrichs: If you give injection at the time of ovariectomy it should last 7-10 days, which would be OK if the mares are released in 2-3 days. Otherwise would need to be given later for a later release, and it would be better not to handle the horses again.

Were the stallions held?

Collins: Depended on the studs (they were doing vasectomies). Some were turned out sooner than the mares, but not always.

Did the mares get back to the same harem group?

Collins: They were not released all at once and this was not monitored as some were adopted.

Griffin: **Is a week enough to heal?**

Weikel: Yes, the healing rate is very quick with colpotomy.

Hinrichs: To be safe maybe one should allow 2 weeks before the mare is repeatedly bred in the wild in order to avoid catastrophe. A stallion can rupture even an intact vagina. It takes a surgical incision 7-10 days to fully heal.

Risk is running through chute once or keeping them in captivity?

Weickel: Checking the BET website, there is a 30 day progestin injection, Altrenogest, that could also be given. Could it promote uterine infection?

Hinrichs: if the uterus was contaminated at surgery, but as noted before, this is unlikely.

King: **Could progesterone injections also be given to control animals** (to reduce any confounding effects of progesterone injection on comparisons of observed animal behavior)?

Hinrichs: This drug has been thoroughly tested in pregnant mares and shown not to be detrimental to the mare or foal.

Mare menopause approach: *Doug Eckery*

- The aim is to develop a vaccine. GonaCon and PZP are currently available and both have been shown to be effective, but for a limited time. PZP prevents fertilization; GonaCon prevents ovulation. A vaccine is only good as long as antibodies can be maintained. PZP, in particular, requires many booster shots. Follicles are constantly replenishing, so mares need a booster throughout their lifetime.
- The idea is to target something earlier in ovarian function. Successful reproduction in female mammals depends on an adequate supply of eggs that are found in primordial follicles. However, there is only a finite supply of eggs in the ovaries, that if destroyed would cause permanent sterilization. Every day a certain number of primordial follicles begins to grow, and only a very few ever reach the final stages of maturation and go to ovulation. The initiation of growth is a committed step and controlled largely by local growth factors. Oocyte-specific growth factors are involved in the early stages of follicular growth. A research team in New Zealand found that a certain group of infertile sheep had a mutation causing infertility. The research goal is to come up with a vaccine to mimic this mutation but for horses. If the primordial follicles do not mature then the animal is sterile. For sterility you need to deplete the ovaries of eggs by directly killing the eggs/primordial follicles or by

causing a mass activation of the primordial follicles (once growth is started it cannot be stopped).

- We are going to test vaccines against oocyte specific growth factors in horses. This will prevent follicular growth and ovulation in the short term, but hopefully will eventually deplete eggs leading to mare menopause, but this is a hypothesis.

Timeline:

- Start research in November by vaccinating mares against the growth factors. After 1 year will conduct a unilateral ovariectomy and look at the ovaries under the microscope. Throughout the year will conduct hormone testing. AMH levels will be measured, as this can be one index of follicular reserve. The project will run for 2 years. Also will track ovarian function through ultrasound and behavior through teasing.

Comments:

Kane: **When would you expect them to be sterile? Are you planning a fertility challenge?**

- We do not expect animals to continue to cycle. The follicles will not produce any steroids so behavior will be changed. Eventually we will conduct fertility testing. It is unknown how long it will take to deplete the ovaries. This is a test to see if the mechanism will work.
- Vaccine and booster will be 6 weeks apart. Next step is to develop a vaccine.

Kane: single shot vaccination is a lofty goal.

Schoenecker: **What happens if given to a pregnant mare and depletes her eggs?**

- The vaccine should have no effect on an existing pregnancy as it is not affecting the corpus luteum.
- The time frame of egg depletion would take longer than the term of a pregnancy, so therefore no effect on the pregnancy.

Kane: **What about the effect on the fetus?**

- Antibodies would probably not pass through the placenta to affect the foal, and probably not in the colostrum long enough to affect the foal's antibodies. But it is unknown whether there would be a long-term effect on the offspring.

How to Perform Hysteroscopy in the Mare

Steven P. Brinsko, DVM, MS, PhD, DACT

Author's address: Department of Large Animal Clinical Sciences, College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, TX 77843-4475; e-mail: sbrinsko@cvm.tamu.edu. © 2014 AAEP.

1. Introduction

Hysteroscopy is not a common procedure in broodmare practice. A thorough breeding soundness examination that includes transrectal palpation and ultrasonography, endometrial cytology, endometrial biopsy, endometrial culture, and vaginal/cervical speculum examination will detect many reproductive maladies frequently encountered in the mare. However, in some circumstances, these more commonly employed techniques are insufficient to clearly identify or ameliorate the problem, and hysteroscopy has been used to achieve this end. In an early study, 17 of 40 mares admitted to a veterinary teaching hospital with a history of infertility had reproductive tracts that were considered normal on palpation, yet hysteroscopy revealed abnormalities in 26 of these 40 mares.[1] Since that time, abnormalities observed through the use of transrectal ultrasonography have either obviated the need for or alternatively prompted the use of hysteroscopy to render a more definitive diagnosis or treatment.

The use of hysteroscopy in the mare was described as early as the 1960s.[2] Subsequently, many authors have published articles on the use of hysteroscopy in the mare for a variety of purposes.[1,3–9] While the term hysteroscopy will be used throughout this manuscript, it is also called uteroscopy and has been referred to as examination of the uterus via fibroscopy, endoscopy, and videoendoscopy in other publications.

2. The Equipment

A flexible videoendoscope, 100 cm in length and 1 to 1.4 cm in diameter, is commonly used for hysteroscopy. The unit should have sufficient light intensity and image quality to optimize visualization of the uterine lumen. Most modern units are equipped with a video monitor, which enhances the examination. The use of recording equipment to capture still and video images is highly recommended to enable review of the procedure and to provide a record of the examination. Ideally, the insertion tube should have a working channel that accommodates ancillary equipment such as catheters, grasping forceps, biopsy forceps, electrocautery loops, and laser fibers.

Since endoscopy equipment is used for examination of a variety of body cavities, it is important that it be thoroughly cleaned and sterilized according to the manufacturer's instructions between uses. Particular attention should be paid to areas where moisture may accumulate, as these sites provide an environment that facilitates the growth of *Pseudomonas aeruginosa*. Persistent endometritis with *Pseudomonas* as well as growth of other organisms has been reported following hysteroscopic proce-

NOTES

dures.[10] If the equipment has undergone chemical sterilization, it is also imperative that the insertion tube, including all of its channels and the water reservoir, be thoroughly rinsed to remove the disinfecting solutions as these chemicals can be very caustic to mucosal tissues.

3. Preparation of the Mare

The mare should be placed in stocks with the tail wrapped and deviated away from the perineal area. Feces should be evacuated from the rectum and the perineum of the mare should be cleansed in an aseptic manner. Sedation and analgesia should be administered. Most practitioners have a favorite sedation protocol, and the following is the author's preferred method. Depending on the size and temperament of the mare, she is administered detomidine HCL[a] (0.006–0.01 mg/kg, IV), and a catheter is placed in the jugular vein. Depending on the anticipated length of the procedure, 5 or 10 mg of detomidine HCL is added to a 500 or 1000 mL bag of saline, respectively, which is then connected to the catheter in a routine manner. The detomidine/saline mixture is then administered by slow drip until the desired level of sedation is achieved. If necessary, more can be administered during the procedure as needed. The author prefers this method because it maintains a more even level of sedation and avoids the wide fluctuations in sedation that can occur over time with repeated larger boluses of sedative. After the mare is sedated and just prior to the start of the procedure, butorphanol tartrate[b] (0.01–0.02 mg/kg) is administered intravenously thought the catheter.

4. Basic Procedure

Under ideal circumstances, at least three people should be present to perform the hysteroscopic procedure; one person remains at the head of the mare for restraint as well as monitoring and administering sedation, one person inserts and maintains the position of the insertion tube through the cervix, and one person operates the steering controls of the insertion tube and directs the overall procedure.

After the insertion tube has been rinsed thoroughly, the image should be "white balanced" to optimize visualization. It is easy to become disoriented once the insertion tube enters the uterus, especially if rotation of the tube has occurred. Therefore it is helpful, prior to inserting the instrument into the mare, for the operator to select a point of reference and become familiar with the directional controls of the steering tube.

A small amount of sterile lubricant is applied to the end of the insertion tube, avoiding contact with the lens, and the assistant wearing a sterile glove and sleeve carries the insertion tube through the vulva and vestibule into the vagina so that the cervix can be visualized (Fig. 1). The cervix is then penetrated and slightly dilated with the index finger, and the insertion tube is passed through the cervix into the uterus. Once inside the uterus, the lumen needs to be distended to allow visualization. While the hysteroscopic procedure can be performed at any time in the mare's cycle, diestrus is preferable because, at that time, the cervix is of sufficient length to be grasped around the insertion tube and maintain uterine distention. Administering progestogens to estrous or anestrous mares for 5 to 7 days prior to the procedure can also accomplish this. In periovulatory mares, the cervix may be sufficiently relaxed that the entire hand carrying the insertion tube can be placed though the cervix into the uterine body and then the hand pulled back against the internal cervical os to act as a plug to maintain distention.

Fig. 1. Endoscopic view of the cervix.

Distention of the uterine lumen can be accomplished by insufflation with filtered air administered via the endoscopic equipment or by a sterile, isotonic fluid such as saline or lactated Ringer's solution (LRS). Note that insufflation with air can cause endometrial hyperemia, which should not be misinterpreted as inflammation. The method of distention depends on clinician preference and the purpose of the procedure. Regardless of which method is chosen, over distention of the uterus should be avoided so as not to cause significant discomfort to the patient or damage to the uterus. One study determined that a hysteroscopy can be performed safely and efficiently within a pressure range of 12.8 to 28.6 mm Hg and that clinical or cardiac signs of discomfort or effects on the circulatory system were only registered after pressures significantly exceeded 100 mm Hg.[11] Precise monitoring of intraluminal pressures is not practical in most clinical environments, so it is recommended to use only the amount of distention necessary to optimize visualization and to continuously monitor the mare for signs of discomfort.

Insufflation allows visualization of normal structures as well as the relative amount and location of

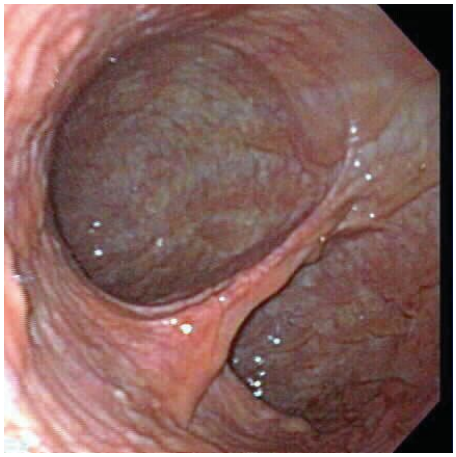

Fig. 2. Bifurcation of the uterine horns viewed after insufflation.

Fig. 3. Uterotubal papilla at the uterotubal junction.

foreign materials such as purulent exudate or blood, etc. Samples of exudate, foreign material, or other abnormalities can be obtained via instruments introduced through the working channel. However, when using insufflation, the lens of the insertion tube may require repeated rinsing to remove mucus or other debris during the procedure. Distention with fluid tends to keep the insertion tube lens free of direct contaminants, but visualization can be compromised if significant amounts of exudate, blood, or other materials become suspended in the distention fluid. If this occurs, drainage or aspiration of the cloudy fluid followed by redistention is recommended prior to proceeding with the procedure. Fluid distention of the uterine lumen can be accomplished using the fluid reservoir or the working channel of the endoscope, but this can take an inordinate amount of time. The author prefers to attach a stallion catheter to the insertion tube with waterproof tape so that the two can be passed through the cervix simultaneously and maintained in proximity. The distal end of a typical IV extension set is then inserted into the belled end of the stallion catheter, and this system is connected to a 5 L bag of LRS or other sterile, isotonic fluid. If drainage of the distention fluid becomes necessary, the extension set can be disconnected and the fluid allowed to escape via gravity flow, or a suction device can be attached to the stallion catheter to facilitate drainage.

Once the uterine lumen is sufficiently dilated, the uterine body and bifurcation of the uterine horns should be visualized (Fig. 2). The insertion tube is directed toward the uterine horn of choice and slowly advanced proximally through the entire length of the horn until the uterotubal papilla at the uterotubal junction (UTJ) is observed. This structure can vary somewhat in appearance being relatively flat and somewhat difficult to visualize in some mares to very prominent in others (Fig. 3). The instrument is then slowly withdrawn to the level of the bifurcation and then the opposite uterine horn is similarly examined. The character and color of the endometrium is observed throughout the examination; it should be relatively uniform in its entirety. The color is typically a pale pink, but the extent of endometrial folds observed can vary with the degree of luminal distention. If the examination is performed during estrus, the surface of the endometrium will typically glisten with mucus, and the endometrial folds will be visibly edematous (Fig. 4).[9] Any abnormalities such as discoloration, ulceration, plaque-like lesions, biofilm, cystic structures, luminal protuberances, adhesions, foreign bodies, or accumulations of blood or exudate should be digitally recorded and sampled as necessary. When the examination is completed and the insertion tube is being removed, the majority of air or fluid used for luminal distention should be removed either passively or by gentle suction. If the fluid distention

Fig. 4. Endometrial folds of the uterus prior to optimal distension.

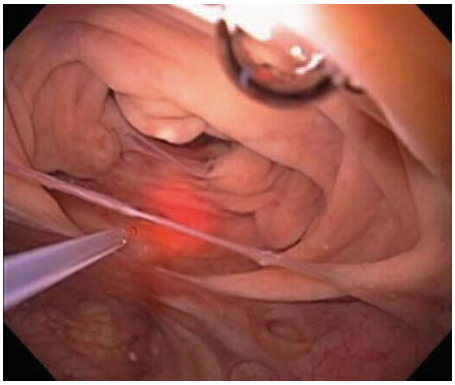

Fig. 5. Laser fiber approaching a thin transluminal adhesion prior to photoablation.

Fig. 7. Multiple transluminal adhesions viewed by hysteroscopy after multilocular fluid filled structures were detected via transrectal ultrasound.

technique was employed, fluid remaining in the bag can then be used to further lavage the uterus.

5. Common Applications

The most common use of hysteroscopy in our practice is for laser ablation of endometrial lymphatic cysts using an Nd:YAG or diode laser. Various methods of cyst ablation using hysteroscopy have been previously described in more detail and improvements in pregnancy rates have been reported following these procedures.[12–16] The cysts are first identified using transrectal ultrasonography, and their size and location are recorded in the mare's record. The mare is prepared as described above, and the entire uterus is examined noting the location of any visible cysts prior to initiating cyst ablation. Either air insufflation or fluid distention can be used. The author prefers to use fluid when possible because, in addition to keeping the lens clean, no smoke is produced while ablating the cyst in the fluid environment as can occur with insufflation, which results in temporary obscurement of the visual field. Another advantage of fluid distention is the beneficial effect of concurrent uterine lavage. Laser ablation can also be used for removal of small transluminal adhesions (Fig. 5). Note, however, that when fluid is used for luminal distention, more wattage will be necessary to achieve the same degree of cauterization as would occur if air insufflation were used.

Hysteroscopy has also been used for direct examination of the endometrium when suspicious, nondefinitive findings are observed via transrectal ultrasonography. Examples include foreign bodies appearing as hyperechoic structures, differentiating of large multiloculated structures as cysts or transluminal adhesions (Figs. 6–8), or suspected uterine tumors.[17–20] Retrieval of foreign bodies and endometrial biopsy procurement via hysteroscopy has recently been described.[8] Attempts to suppress estrus with marbles has been attempted by

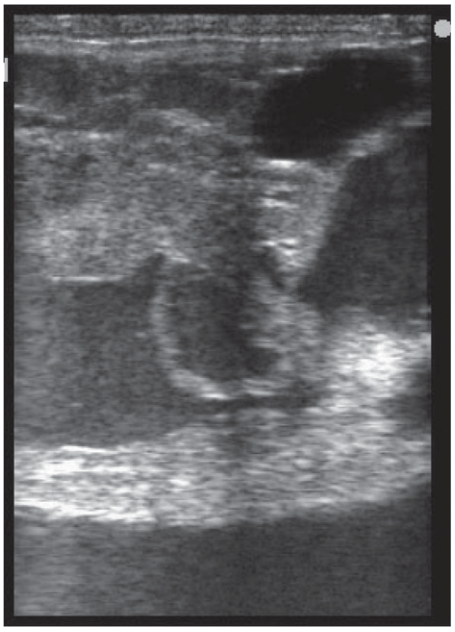

Fig. 6. Ultrasonographic image of the uterus of a mare with large multilocular fluid filled structures.

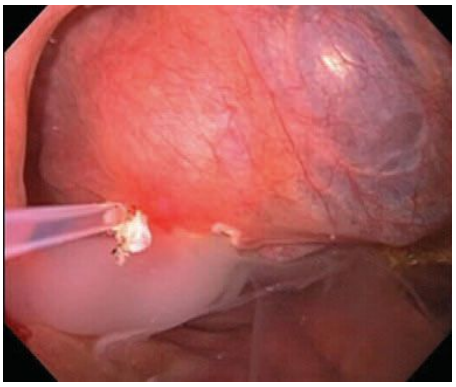

Fig. 8. Purulent fluid being released during laser photoablation of a large transluminal adhesion.

a number of practitioners, sometimes with disastrous results, when multicolored marbles are used and they disintegrate within the uterine lumen causing significant damage. Although large fragments could be retrieved via hysteroscopy, the disintegration often results in numerous minute glass fragments that become embedded in the endometrium and are virtually impossible to remove. While biopsies can be obtained via flexible instruments passed through the working channel, samples obtained are typically small and shallow whereas using a standard biopsy instrument passed along the side of the insertion tube will provide superior samples.[8,21]

Two manuscripts describing direct hysteroscopic insemination of the UTJ with low numbers of sperm were presented at the AAEP meeting in 1998.[22,23] However, achieving direct cannulation of the UTJ is too difficult for routine use and, subsequently, deposition of semen on or near the UTJ was shown to be an effective method of low dose, deep horn insemination.[24] Comprehensive summaries of hysteroscopic insemination studies have been published.[25–27] While hysteroscopy insemination allows direct visualization of the UTJ, semen deposition at the tip of the uterine horn using a manual, transrectally guided technique has been shown to be equally effective and is more economical and efficient for most practitioners.[28]

Recently, Inoue described direct cannulation of the UTJ and deposition of dye into the oviduct as a method of determining tubal patency.[29] He proposed that the difficulty others have experienced in cannulating the UTJ was a result of over insufflation of the uterus, which makes it difficult to center the UTJ in the center of the endoscopic image. Therefore, it was recommended that the endoscope be passed up the uterine horn to the level of the UTJ with minimal insufflation of the uterus.

Summary

This study was aimed to examine the effect of ovariectomy on visceral fat, serum adiponectin levels and lipid profile. Forty-five female Sprague Dawley rats were divided into three groups (n=15 each): ovariectomized group (OVX), ovariectomized plus estrogen-treated group (OVX+E_2), and sham-operated group (SHAM). Body weight, abdominal adipose tissues, serum adiponectin and lipid profile were measured and compared among the groups after three-month feeding post-surgery. Significant increases in body weight and visceral fat were found in ovariectomized rats when compared with sham-operated ones and significant increases were also observed in serum adiponectin, triglyceride and very low density lipoprotein cholesterol levels in ovariectomized rats. Body weight, visceral fat and serum adiponectin levels were profoundly reduced in OVX+E_2 group as compared with OVX group. It was concluded that ovarian hormone deficiency induced by ovariectomy leads to significant increases in body weight and visceral fat, along with increased serum adiponectin, triglyceride and very low density lipoprotein cholesterol levels in rats. Attenuation in these changes can be achieved by estrogen supplementation.

Key words

ovariectomy estrogen post menopause serum adiponectin visceral fat

Urinary androgen concentrations and social status in two species of free ranging zebra (*Equus burchelli* and *E. grevyi*)*

M. Chaudhuri†§ and J. R. Ginsberg‡¶

†*New York Zoological Society, Bronx, NY 10460, USA; and* ‡*Department of Biology, Princeton University, Princeton NJ 08544, USA*

Summary. In both species of zebra, breeding males had higher urinary androgen concentrations (ng androgens/mg Cr) than did non-breeding bachelor males (30·0 ± 5·0 (N = 9) versus 11·4 ± 2·8, (N = 7) in the plains zebra; 19·0 ± 2·2 (N = 17) versus 10·7 ± 1·2 (N = 14) in the Grevy's zebra). In the more stable family structure of the plains zebra (single male non-territorial groups) variations in androgen concentrations could not be ascribed to any measured variable. In the Grevy's zebra, androgen values were significantly lower in samples taken from territorial (breeding) males which had temporarily abandoned their territories (N = 4) and the urinary androgen concentration for a male on his territory was negatively correlated with the time since females last visited the territory.

Keywords: zebra; testosterone; androgens; territoriality; social behaviour; dominance

Introduction

Members of the family Equidae show two patterns of social organization (Klingel, 1975). In the first type, typified by the plains zebra, *Equus burchelli*, a single breeding male is found in constant association with a fixed group of 1–6 unrelated females and their offspring. These groups, or harems, show little sight fidelity. Mating activity shows seasonal peaks coincident with periods of food abundance, but mating may occur at any time throughout the year (Klingel, 1969). Bachelor males remain in fixed membership groups separate from harems and have never been observed mating with adult females (Klingel, 1969). In the second type of social organization, represented in this study by the Grevy's zebra, *Equus grevyi*, there are no permanent bonds between any two individuals nor is there any seasonality in breeding (Klingel, 1974; Ginsberg, 1987, 1989). Breeding males defend territories in which they retain exclusive access to oestrous females when present. Klingel (1974) never observed bachelor males mating. Of 94 copulations observed by Ginsberg (1987), 87 (93%) were made by territorial males while on their territories.

For this study, data were collected from a free ranging population of zebras in their natural habitat to examine whether there is a potential hormonal basis for both intra- and inter-specific differences in male behaviour. Data from other studies suggest that it is likely that there is an endocrinological basis to the different behaviours observed in the various groups of males. In the congeneric domestic horse, *E. caballus*, the secretion of luteinizing hormone and testosterone show seasonal variations (Berndtson *et al.*, 1974, 1983) as do seminal and behavioural characteristics

(Pickett *et al.*, 1970; Thompson *et al.*, 1977) suggesting an endocrine mechanism. The seasonality of these changes coincides with the breeding cycles of females.

Materials and Methods

Study area. Data were collected in the Buffalo Springs Reserve, in the region around the town of Archer's Post, Kenya (37°30′ E,0°40′ N). The study area, while climatologically homogeneous (dry and hot), is vegetationally diverse. This diversity is apparent even on a small scale (Barkham & Rainy, 1976). Average rainfall for the Archer's Post Station is 365 mm (Government of Kenya, 1984) with the maximum rainfall occurring in two seasons, March/April and October/November.

Definition of behavioural status of males. Urine samples were collected from known individuals identified by their unique stripe patterns (Peterson, 1972; Klingel, 1974). In both species, males were placed into one of two categories, breeding or bachelor, according to differences in behaviour. In the plains zebra, an adult male was considered to be a breeding, or harem, male if he was seen in association with a particular group of females and juveniles on at least 90% of all observations. In contrast, bachelor males were nearly always observed in fixed membership groups with other bachelor males.

In the Grevy's zebra, neither bachelor males nor territorial males were seen in consistent association with other individuals. Territorial males make frequent forays off their territories and were usually seen in association with bachelor males at these times (Ginsberg, 1987). While on territory, the breeding male exhibited typical patterns of behaviour (calling, marking), a distinctive posture, and dominance over all other individuals (Klingel, 1974).

Behavioural measurements were taken on 1084 individual Grevy's zebra identified by their stripe patterns. Zebra stripes are individually distinct (Klingel, 1974) and identifications were made with an accuracy of at least 98% (Ginsberg, 1987). Information was collected daily on the distribution and identity of the zebra in the study area. Point-sample data, collected for 9795 sightings (5061 males; 4734 females) during the entire study, provide records of associations of individual zebra. Of course, not all zebra were identified on all days nor, given the scope of the study, were animals observed continuously.

Urine collection. In both species, urinary testosterone concentrations of potentially breeding males (territorial for the Grevy's zebra, and harem breeding for the plains zebra) were compared to those of non-breeding males. Within the sub-sample of breeding males, variations in androgen concentrations were examined to determine the effect of time of day, season, and association with both bachelor males and females. Urine was collected from zebras in April, May and June of 1985. Males were observed urinating and the urine was aspirated from the ground using a sterile 10-ml syringe. Samples were collected within 5 min of urination and were stored in glass jars, packed on ice and frozen on return to camp at −5°C. Specimens were transferred to Nairobi on a monthly basis and stored at −20° C. At the time of collection, the following data were recorded: time of day; individual identification; group composition (no. of males, no. of females, presence/absence of oestrous females); breeding male or bachelor male; if territorial, on or off territory. In addition, for territorial male Grevy's zebra, the time since last association with either bachelor males or females was calculated from data collected on daily surveys of all individuals within the study area.

During the period in which urine samples were collected, none of the plains zebra harem males were observed in association with oestrous females. Because the duration of oestrus in the plains zebra is brief ($\simeq$ 1 day, J. R. Ginsberg, unpublished data), the possibility that a harem male was in association with an oestrous female the day preceding collection of a sample cannot be eliminated.

Androgen assay. All androgen values are expressed relative to urinary creatinine (Cr) concentrations to allow for correction of variation in urinary water content. The procedure of Taussky (1954) was used to measure Cr and the sensitivity of the assay was 0·1 mg/ml urine.

The urine samples were subjected to acid hydrolysis. An aliquant of each urine sample (0·4 ml) was diluted 1:2·5 with water and 0·2 ml 12 N-HCl; 1500 c.p.m. [^{3}H]testosterone/0·1 ml were added for recovery calculations. This mixture was incubated in a boiling water bath for 15 min. After neutralization with sodium hydroxide, an aliquant of this hydrolysed urine (0·05 ml) was extracted twice with 5 ml freshly opened diethyl ether. The extract was dried under a stream of nitrogen and then reconstituted in 1·0 ml assay buffer (0·1 M-phosphate, pH 7·0, containing 0·9% (w/v) sodium chloride, 0·01% sodium azide and 1% gelatin). A 0·5 ml sample was counted for recovery while 0·05 ml was assayed for androgens by radioimmunoassay as described by Janne *et al.* (1974). Two samples were run from each sample and no inter-assay differences were found. The antiserum was raised in rabbits against testosterone-17-hemisuccinate–BSA. The major cross-reactions were 18·2% with 5α-dihydrotestosterone and 12·9% with 5β-dihydrotestosterone. The assay tubes containing the sample, antibody, and [1,2,6,7,16,17-^{3}H]testosterone (sp. act. 135 Ci/mmol: New England Nuclear, Boston, MA, USA) were incubated for 2 h at 4°C. The separation of antibody-bound and free steroid was achieved by addition of 0·5 ml charcoal–dextran (0·5% charcoal Norit A, 0·05% dextran in the assay buffer) during a 15-min incubation at 4°C. After centrifugation for 15 min, the supernatant was decanted and mixed with scintillation cocktail and counted for 5 min. The standard curve ranged from 3 to 1000 pg/tube and the lowest detectable sample measured was 3 ng/ml urine. Serial dilutions of hydrolysed zebra urine showed parallelism with the standard curve. All the samples were run in a single assay and the mean ± s.e.m. recovery of titrated testosterone added to the hydrolysed urine was 72·9 ± 1·8%, n = 53). Various known amounts of unlabelled

testosterone were also added to a pool of zebra urine before hydrolysis. The mean ± s.e.m. recovery was 77·8 ± 8·9% (n = 8).

Body size. Body size was estimated using photometric analysis for the Grevy's zebra. Complete details of the method are given by Ginsberg (1987). Linear girth, the distance from the withers to the belly, was estimated and used as the measure of body size. For any particular individual, estimates of linear girth had an error of ≃8%. Given that arid-zone adapted equids can vary in weight up to 20% due to dehydration (Maloiy, 1970), linear girth measurements appear to provide an accurate measure of relative size.

Statistical analysis. Statistical analyses were performed on an Apple Macintosh S.E. running Statview software (Abacus Concepts, 1986). As data were not found to deviate from a normal distribution, parametric statistics were used throughout. Results are expressed as the mean of all values ± the standard error of the mean (s.e.m.).

Results

Plains zebra

Harem (breeding) males had significantly higher androgen concentrations than did bachelor males (Fig. 1: 30·0 ± 5·9 ng/mg Cr, N = 9, versus 11·4 ± 2·8 ng/mg Cr, N = 7; d.f. = 13, t = 3·23, $P < 0·01$). Among harem males, neither the time of day at which samples were collected (r^2 = 0·01, $P > 0·50$ nor the number of females in a male's harem (r^2 = 0·16, $P > 0·30$) had any significant effect on androgen concentrations. No data on body size were available for plains zebra.

Grevy's zebra

Territorial males had higher concentrations of androgens than did bachelor males (Fig. 1: 19·0 ± 2·2 ng/mg Cr, N = 17, versus 10·7 ± 1·2 ng/mg Cr, N = 14; d.f. = 29, t = 3·13, $P < 0·01$). Samples were collected from 4 territorial males who were on forays off their territories. These results show that when a territorial male is off his territory he is likely to have reduced androgen values compared to concentrations in the same male when he is on territory (Fig. 1: paired Student's t test, d.f. = 3, t = 2·49, $P < 0·05$). There was no significant difference in androgen concentrations between off-territory males and bachelor males (d.f. = 16, t = 0·93, $P > 0·30$).

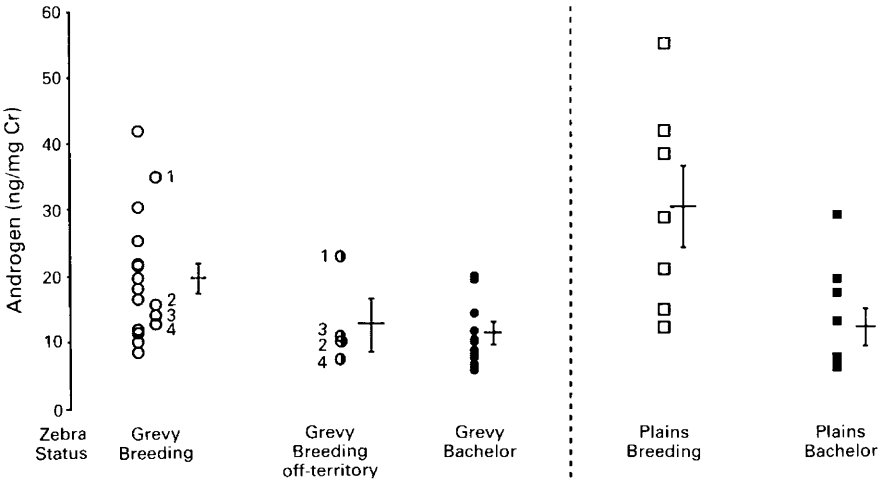

Fig. 1. Urinary androgen concentrations (mean ± s.e.m.) for two species of zebras. For Grevy's zebra, samples were collected from 4 breeding individuals both on and off their territories. In the first column (open circles), these samples are numbered and are slightly off-set to the right. Samples in column two for corresponding males are similarly numbered.

In samples taken from territorial males, neither the presence of females (N = 4) at the time of sampling (d.f. = 15, $t = 0{\cdot}77$, $P > 0{\cdot}40$), nor the presence of bachelor males (N = 3) at the time of sampling (d.f. = 15, $t = 0{\cdot}64$, $P > 0{\cdot}50$), or the time of day at which samples were collected ($r^2 = 0{\cdot}14$, $P > 0{\cdot}10$) affected androgen concentrations.

There was no correlation of urinary androgen concentrations with the time since last association with bachelor males (d.f. = 16, $P > 0{\cdot}10$) but there was a negative correlation between urinary androgen concentrations and the time since a territorial male was last seen in association with at least one female (Fig. 2: $y = -0{\cdot}43x + 22{\cdot}2$, $r^2 = 0{\cdot}26$, $P < 0{\cdot}05$).

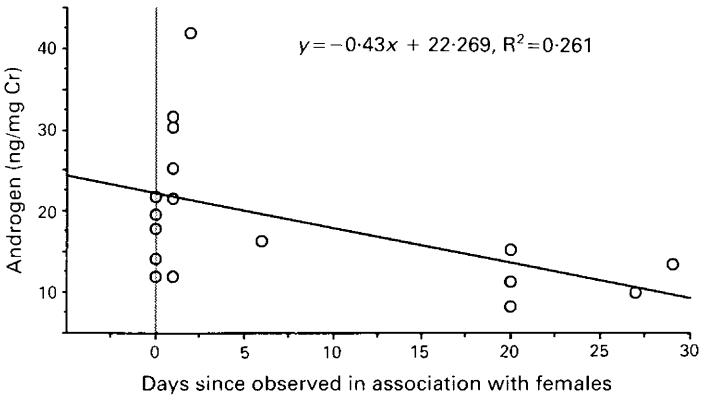

Fig. 2. The effect of absence of females on testosterone concentration in territorial Grevy's zebra males.

Among bachelor males and territorial males, body size had no effect on urinary androgen concentrations. When males of both types were simultaneously included in the analysis, there was a strong correlation between body size and urinary androgen concentrations (d.f. = 27, $y = 0{\cdot}951x - 48{\cdot}5$, $r^2 = 0{\cdot}25$, $P < 0{\cdot}01$).

Discussion

The results of this study indicate that, despite marked differences in social organization, breeding males of both the Grevy's and plains zebra exhibit similar endocrine changes. In both species, males that have access to females (i.e. potentially breeding males) excrete more androgens than do non-breeding males. Hence, there is an endocrinological correlation with social dominance, as measured by access to sexually receptive females, which appears to be consistent across breeding systems.

The use of a urinary assay for androgens had several advantages. The method allowed samples to be collected, without immobilizing animals, from a large number of individuals in free-ranging wild populations of two sympatric species of zebra. One of the species, the Grevy's zebra, is classified as endangered (Thornback, 1977). As immobilization of wild equids is often difficult (King & Klingel, 1965), collection of samples on the scale required would have been impossible. Furthermore, the fluctuations observed in plasma androgen measurements (Katangole *et al.*, 1971; Bartke *et al.*, 1973) are minimized using urinary samples since they presumably reflect androgen secretion over a period of several hours. It was assumed that most of the androgens were of testicular origin as in other species the contribution of the adrenals is minimal.

The correlation between dominance and androgen concentrations has been observed in a wide variety of other ungulate families including bovids (impala, *Aepyceros melampus*: Bramley &

Neaves, 1972), cervids (red deer, *Cervus elephus*: Lincoln *et al.*, 1972; white-tailed deer, *Odocoileus virginianus*: Miller *et al.*, 1987) and elephants (African elephant, *Loxodonta africana*: Poole *et al.*, 1984). In experiments with antelopes, territorial males had higher plasma testosterone values than did bachelor males in response to gonadotrophin-releasing hormone (Illius *et al.*, 1983).

In the Grevy's zebra, the results suggested further endocrine–behavioural interrelationships. That the concentration of androgen appeared to decline when females had not recently been present suggests that social stimuli may be a factor influencing androgen secretion. When females have not visited a territory for some time, males will temporarily abandon their territories (Ginsberg, 1987), and so the fact that males which have temporarily abandoned their territories have lower concentrations of androgens is not surprising.

That association with other males does not affect androgen concentrations may be due to small sample sizes. A territorial male may spend up to several weeks on territory without being in association with either males or females (Ginsberg, 1987). Hence, another way to evaluate the effect of conspecifics on androgen concentrations is to examine the relationship between urinary androgen concentrations in samples taken from territorial males as a function of the time since their last association with conspecifics.

While these data demonstrate that there is an endocrinological basis to dominance in zebra, the direction of causality cannot be determined from these observations. In a variety of other species, sexual activity (rabbit: Ågmo, 1976; ram: Sanford *et al.*, 1974; Gonzalez *et al.*, 1988; boar: Liptrap & Raeside, 1978; bull: Katangole *et al.*, 1971; mouse: Coquelin & Bronson, 1980; rat: Kamal & Frankel, 1978; rhesus monkey: Herndon *et al.*, 1981) or merely exposure to females (ram: Gonzalez *et al.*, 1988) or their scent (hamster: Macrides *et al.*, 1974) led to elevated concentrations of serum testosterone. In boars, aggressive encounters also led to increased concentrations of testosterone in the blood (Liptrap & Raeside, 1978); however, in the lesser mouse lemur, only dominant males showed higher levels of testosterone after aggressive encounters (Peret, 1985). In other studies sexual activity (bull: Price *et al.*, 1986; ram: Moore *et al.*, 1978) and aggressive encounters (bull: Price *et al.*, 1986) had little or no effect on serum testosterone concentrations.

It remains to be determined whether, in zebra, increasing concentrations of androgens cause an animal to be dominant, or whether high androgen concentrations are characteristic of dominant males. It is tempting to suggest that proximity to females raises androgen concentrations which, in turn, increases aggression enabling the dominant male to defend his mate. However, further research is required to confirm this hypothesis.

Physical factors could also have an effect on androgen concentrations. As all samples were collected at the same time of the year, differences observed cannot be ascribed to seasonality. In red deer stags, testosterone was correlated with aggressive behaviour, while dominance position was affected by other variables including weight, antler size, age and experience in addition to testosterone concentrations (Lincoln *et al.*, 1972). In this study, within a reproductive class (territorial or bachelor), there was no correlation between size and androgen concentrations. When reproductive classes were pooled, there was a significant effect of body size on androgen level. However, as territorial males are larger than bachelor males (Ginsberg, 1989), the size and reproductive class are highly auto-correlated. Furthermore, among territorial males, male reproductive success is not correlated to body size (Ginsberg, 1989). Given the intra-individual variation in urinary androgen concentrations among males on and off their territories, it seems unlikely that body size has an independent significant effect.

The results of this study demonstrate that, in zebras, androgen values and the reproductive status of individual males are inter-related. In the more stable family structure of the plains zebra, in which association of a breeding male and his females is essentially constant, little can be concluded other than that breeding males have higher androgen concentrations than do bachelor males. The fluid social organization of the Grevy's zebra allows a more detailed analysis of how different social variables affect androgen values. For this species we show that the hormone concentrations changed with the breeding status, and social situation, of the male being studied.

We thank the Population Council for assistance with the hormone assays; Dr R. B. Thau for critical advice on writing the manuscript; Ms Emilee Carrasco for technical assistance; S. K. and W. R. Ginsberg for help with the collection and transport of specimens; and the Office of the President of the Republic of Kenya, the Wildlife Conservation and Management Department, Kenya, the Department of Zoology, University of Nairobi, and Princeton University for sponsoring this research. M.C. was supported by grants from the Marilyn M. Simpson Charitable Trust and the Bay Foundation. Field research was funded by the National Geographic Society (grants 3022-85 and 2638-83), and the New York Zoological Society.

Neutering affects mRNA expression levels for the LH- and GnRH-receptors in the canine urinary bladder

V.A. Coit, F.J. Dowell, N.P. Evans *

Division of Cell Sciences, Institute of Comparative Medicine, University of Glasgow Veterinary School, Bearsden Road, Glasgow G61 1QH, UK

Received 9 November 2007; received in revised form 17 June 2008; accepted 18 June 2008

Abstract

Neutering a bitch increases the incidence of acquired urinary incontinence (AUI) 20-fold. Mechanistically this effect is thought to be related to altered steroid/reproductive hormone concentrations and a recent study showed that gonadotrophin releasing hormone (GnRH) analogue treatment improved continence in bitches with AUI. The aim of this study was to examine mRNA expression levels for luteinizing hormone (LH)- and GnRH-receptors in the canine bladder and the correlation between these and *in vitro* contractility of the bladder using age matched entire and neutered, male and female canines and canines with AUI.

Biopsies from the dome of the bladder were dissected post mortem with informed owner consent. mRNA expression for LH- and GnRH-receptor was quantified by rtPCR (relative to β-actin). Contractility was assessed (cumulative concentration response curve for carbachol) in strips of bladder muscle using standard protocols.

Analysis of variance (Tukey post-test) demonstrated thet neutering was associated with significantly increased levels of expression of LH- and GnRH-receptor mRNA in both sexes ($P < 0.01$). mRNA expression for both receptors was significantly higher in female versus male canines. Neither effect was affected by animals' age and/or weight. A significant inverse correlation (Spearman's test) was found between bladder contractility and mRNA expression for both receptors. This effect was most pronounced in canines with AUI which demonstrated the highest mRNA expression levels yet had the lowest contractility of all animals studied. This suggests that increased LH- and GnRH-receptor mRNA expression is associated with changes in bladder function that increase an animal's predisposition to develop AUI.

1. Introduction

Acquired urinary incontinence (AUI) is a debilitating and so far incurable condition that causes significant welfare problems. Two diverse populations have been identified that are particularly susceptible to AUI, post-menopausal women and spayed female canines. Information relating to the exact pathophysiology of the condition in these two groups is not understood well enough to allow determination of commonality of cause; however, both groups are subject to a reduction in gonadal steroids and associated endocrine changes.

Urinary incontinence (UI) is defined as the involuntary leakage of urine [1] and, in the bitch, is an increasingly recognised clinical problem with severe welfare implications that can lead to the ultimate

doi:10.1016/j.theriogenology.2008.06.093

euthanasia of the animal. Interestingly, AUI is reported to affect up to 20% of neutered bitches [2] but is seen in less than 1% of intact bitches [3] and is rarely reported in male canines regardless of gonadal status. A direct relationship between neutering and AUI has been reported [4] which is proposed to occur as a consequence of hormonal, vascular or neurological changes [5], rather than mechanical damage of the lower urinary tract, sustained during surgery [6]. Incontinence in the neutered bitch is frequently associated with a decrease in maximal urethral closure pressure [7,8], however, as this is not a defining characteristic of AUI, multiple causative factors are likely to be involved, not all of which will be a consequence of gonadectomy. It has thus been hypothesized that factors in addition to those that decrease urethral closure pressure, lead to a bitch's developing urinary incontinence after neutering. Previous *in vitro* studies have shown that neutering a canine of either gender leads to a decrease in maximal contractile response of the detrusor muscle to both muscarinic and electrical field stimulation as well as a decreased sensitivity to muscarinic stimulation [9]. These decreases in contractile function *in vitro* are similar to those reported in post-menopausal women who suffer from UI due to impaired contractility of the bladder [10].

Given the commonality of endocrine change in the two populations identified as being susceptible to AUI, it is now a widely held hypothesis that the condition may be due to, or be exacerbated by, hormone-mediated effects. This view is supported by the fact that a pharmacological treatment for AUI in the bitch, is steroid replacement [11]. In both spayed bitches and post-menopausal women there is a deficiency of endogenous gonadal steroid hormones which decreases or removes the normal negative feedback to the hypothalamo-pituitary axis, and results in greatly increased production and secretion of gonadotrophin releasing hormone (GnRH) from the hypothalamus, and increased secretion of the pituitary gonadotrophins (luteinizing hormone (LH) and follicle stimulating hormone (FSH)) [12–18]. This increase in plasma concentrations of LH and FSH post-neutering has been demonstrated to have a direct relationship with the development of urinary incontinence in the bitch [19]. A recent paper has described the clinical use of GnRH analogues to decrease LH and FSH concentrations in neutered female canines suffering from AUI. The results of this study also indicated that GnRH analogue treatment resulted in clinical continence, or a decrease in incontinence, during the treatment period [12,13]. This result would suggest that the increase in the concentrations of either GnRH and/or the pituitary gonadotrophins could be a causative factor for AUI in the bitch. Whilst GnRH and the gonadotrophins are classically thought of as hormones of the hypothalamo-pituitary-gonadal axis, the presence of their receptors in tissues such as skin [20], reproductive tract, prostate and mammary gland [21,22] as well as the urinary bladder [23–25] would suggest more widespread actions. In particular the presence of receptors within the urinary tract would indicate that altered concentrations of gonadotrophins could induce local effects within the bladder which could affect function. As specific tissue action and function rely upon the presence of specific receptors in the tissue it is possible that changes in either absolute receptor numbers or receptor–ligand concentration could influence the action of a tissue. In this regard a study in women has reported a decrease in LH-receptor numbers in the bladder of post- compared to pre-menopausal women [25], and a number of recent studies in the canine have reported either a decrease [24,26] or no effect on LH-receptor mRNA concentrations after neutering [17]. However, there are no published reports of mRNA levels for LH-, FSH- or GnRH-receptors in the bladder of bitches known to be suffering from AUI or the correlation between detrusor contractility, a factor known to be involved in UI [10,27], and receptor mRNA expression levels within the urinary bladder.

The aim of this study was to determine the effects of gonadal status and gender on the expression levels of GnRH-, LH- and FSH-receptor mRNA in the canine urinary bladder and to investigate whether these levels are altered in individuals suffering from AUI. A further aim was to see if there is a correlation between the expression of the mRNAs for these receptors and maximal contractility of the bladder, using age matched groups of entire and neutered, male and female canines.

2. Materials and methods

2.1. Animals and tissues

The study was approved by The University of Glasgow Veterinary School's ethical review committee. A total of 78 canines were included in the study, with a mean age of 6.0 years (range 1–16 years) and a mean weight of 22.7 kg (range 8–50 kg). The majority of canines were cross bred, with no pedigree breeds appearing more than once.

In all cases tissue was collected from canines euthanized (intravenous overdose of pentobarbatone),

with full informed owner consent, for reasons other than scientific investigation. The majority of animals were destroyed for severe behavioural problems, the remainder for a number of different complaints, none of which involved the urinary system. In all cases a detailed history of each animal was taken and, within 2 h of death, a gross post mortem study was performed. None of the animals used in the study were receiving medical treatment in the 7 days prior to euthanasia and there was no evidence of previous medical therapy in at least the month prior to this. Biopsies were collected in the area of the bladder dome and samples either stored at 4 °C in Krebs solution for tissue bath studies or immediately frozen and stored at −80 °C until required for mRNA studies. Any animal with a history or signs of gross pathological urinary, neurological or reproductive tract disease (e.g. tumours, cystitis, pyometra) were excluded from the study (except for those suffering from AUI—see below). The remaining animals were split into five groups depending on sex and gonadal status: entire males (ME), entire females (FE), neutered males (MN), neutered females (FN) and neutered females known to be suffering from AUI (FN AUI). All of the entire bitches were considered to be in anoestrous, as the ovaries showed no signs of follicular activity or of an active corpus luteum and all of the neutered animals were at least 6 months post-gonadectomy (determined by history and clinical examination). A diagnosis of AUI was made on the basis of history and clinical signs at time of euthanasia, coupled with full gross post mortem results that ruled out other causes of UI in the bitch such as ectopic ureters, kidney disease, uroliths, cystitis and gross abnormalities of the urinary system.

Ovarian tissue as well as skin biopsies, from the shoulder and groin regions were collected from a subset of animals included in the study, as a control for FSH-receptor mRNA expression [28]. Ovarian and skin samples were handled and stored as described above.

2.2. mRNA extraction and quantitative reverse transcription PCR

Biopsies where placed in 1 ml ice cold TRIzol reagent (Invitrogen, Paisley, UK), homogenised and RNA extracted according to the manufacturers protocol. After extraction, RNA was suspended in 40 μl RNase-free water and the concentration of RNA determined using a NanoDrop ND-1000 spectrophotometer. The purity of RNA (A_{260}/A_{280}) was greater than 1.9 in all samples. 1 μg of each RNA sample was reverse transcribed into cDNA using random hexamers (Promega, Southampton UK), Moloney-Murine Leukaemia virus (M-MLV) reverse transcriptase (Invitrogen, UK) and Rnasin (Promega, UK), as described previously [28]; final reaction volume of 24 μl. Quantitative real time taqman PCR (qPCR) was performed on cDNA for GnRH-, LH- and FSH-receptor with β-actin as the housekeeping gene using the Amplitaq Gold kit (Applied Biosystems, Warrington, UK) and a Strategene MX 3000P thermal cycler. The primers and probes for the three receptor mRNAs were as described by Welle et al. [20], sourced from Eurogentech (Southampton, UK). Prior to use in the current experiment the concentration of primers and florescent FAM-labelled probes against LH-, GnRH- and FSH-receptor mRNAs [20] were optimised relative to the housekeeping gene β-actin, to ensure that amplification of each of the genes of interest matched that of the housekeeping gene. All probes used were at a final concentration of 530 nM, with forward (f) and reverse (r) primers at: LH- and FSH-receptor mRNAs 1000 nM (f), 800 nM (r), GnRH-receptor mRNA 660 nM (f), 800 nM (r), β-actin mRNA 800 nM (f and r). All samples were run in duplicate, PCR conditions used were an initial step of 95 °C for 10 min followed by 45 cycles of 95 °C for 30 s and 60 °C for 1 min. Non-template controls were included for each primer pair to check for significant levels of any contaminants and in all cases were negative.

2.3. Tissue preparation for tissue bath studies

Tissue was used within 48 h of collection. Following removal of the lining urothelium strips of smooth muscle (2 mm × 10 mm) were dissected from the dome of the bladder. The strips were mounted under 4 g resting tension (the optimum tension demonstrated in preliminary previous length-tension studies) on a fixed hook in a 15 ml organ bath bathed at 37 °C in Krebs solution (NaCl 118 mM, KCl 4.8 mM, $CaCl_2$ 2.5 mM, $MgSO_4$ 1.2 mM, KH_2PO_4 1.2 mM, $NaHCO_3$ 24 mM and glucose 11 mM) gassed with 95% O_2/5% CO_2. Tension was measured with a BIOPAC TSD125C isometric force transducer and displayed using the AcqKnowledge 3.8.1. Biopac data acquisition system (Linton Instruments). Tissues were allowed to equilibrate for 60 min before experiments were begun, during which time the resting tension was re-adjusted to 4 g if required [9]. For all studies, a minimum of 2 muscle strips per animal were included.

2.4. Assessment of carbachol-induced contraction

To determine the response to the non-specific muscarinic agonist carbachol, cumulative concentration

Table 1
Age and weight of animals, by group.

	ME ($n = 27$)	MN ($n = 17$)	FE ($n = 18$)	FN ($n = 13$)	FN AUI ($n = 3$)
Age (years)	5.6 ± 0.7	5.8 ± 0.9	6.1 ± 1.0	6.5 ± 1.0	4.3 ± 2.0
Weight (kg)	23.7 ± 1.8	27.4 ± 3.2	21.9 ± 2.2	21.1 ± 3.1	17. ± 5.0

Mean ± S.E.M. values for age and weight in groups of entire and neutered, male and female canines, and neutered bitches identified as suffering from AUI (ME, MN, FE, FN and FN AUI, respectively). n = number of animals.

response curves to carbachol (1 nm–30 μM) were generated in strips of bladder smooth muscle. Maximal tension was recorded and data calculated as grams tension produced per milligram of wet tissue.

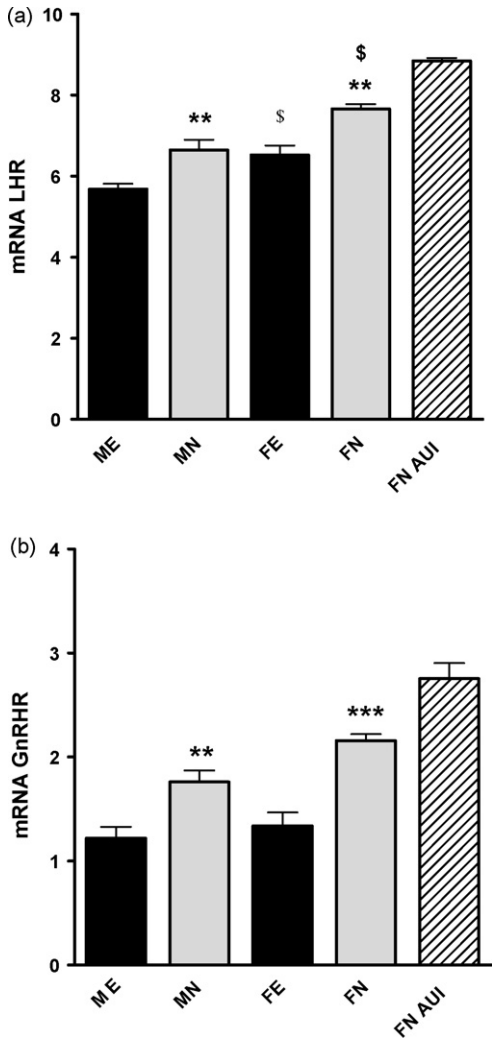

Fig. 1. Mean (±S.E.M.) mRNA expression for: (a) LH-receptor and (b) GnRH-receptor, in entire and neutered male and female canines and neutered female canines identified as suffering from AUI. mRNA values are logarithmically transformed. $^{***}P < 0.001$, $^{**}P < 0.01$ compared entire of same gender. $^{\$}P < 0.05$ compared to male animals of same gonadal status.

2.5. Statistical analysis

Results for both mRNA expression levels and contraction to carbachol were analysed against both age and weight using multivariant analysis with $P < 0.05$ considered significant.

Results are given as mRNA expression levels relative to β-actin using the comparative C_T method (User Bulletin no. 2, PE Biosystems, UK). Data was ln-transformed prior to statistical analysis to equalise the variance between groups and data compared by two-way ANOVA for effects of gender and gonadal status. Post hoc comparisons were conducted using Tukey's test with a significance threshold of $P < 0.05$.

To examine relationships between the levels of mRNA expression of the hormone receptors studied and the ability of the detrusor to contract when stimulated with carbachol, mRNA expression levels of each hormone receptor were plotted against maximal contraction (as grams of tension produced per milligram of wet tissue) and tested for a correlation using Spearman's test with a significance threshold for P (two tailed) <0.05.

3. Results

The mean age and weight of the 78 canines included in this study, 27 entire males (ME), 17 neutered males (MN), 18 entire females (FE), 13 neutered females (FN), and 3 neutered females known to suffering from AUI (FN AUI) are presented in Table 1. There was no statistical difference between the mean ages and weights for the five groups.

The mean levels of mRNA expression for LH- and GnRH-receptor are shown in Fig. 1a and 1b, respectively. Two-way ANOVA indicated significant effects of gonadal status on the expression of the mRNAs for both LH- and GnRH-receptor, whilst there was an additional effect of gender on the expression of LH-receptor mRNA. There was no interaction between the effects of gonadal status and gender. Neutering was associated with significantly ($P < 0.01$) higher levels of mRNA expression for both LH- and GnRH-receptor in

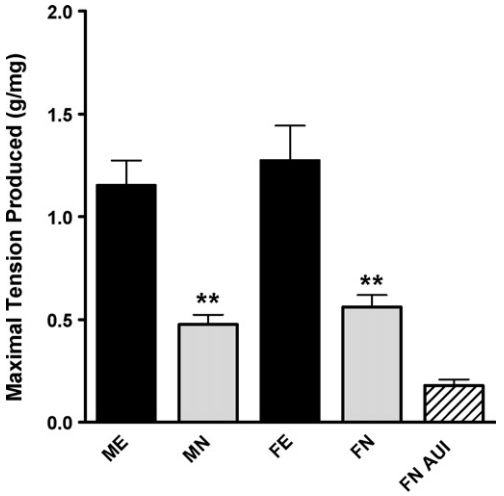

Fig. 2. Mean (±S.E.M.) maximal tension values (g/mg wet tissue) in response to carbachol in entire and neutered male and female canines and neutered female canines identified as suffering from AUI. $^{**}P < 0.01$ compared entire of same gender.

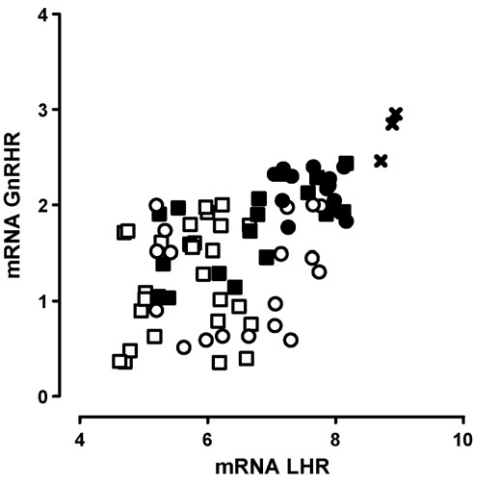

Fig. 3. Correlation between mRNA expression levels of LH- and GnRH-receptor ($P < 0.001$, $r = 607$). (□) Male entire, (■) male neuter, (○) female entire, (●) female neuter, and (×) AUI female neuter.

both genders. Furthermore, female animals showed significantly ($P < 0.05$) greater levels of mRNA expression of LH-receptor, regardless of gonadal status, than their male counterparts (Fig. 1a).

The mRNA expression levels for both LH- and GnRH-receptor for the females identified as AUI were the highest of all the animals in the study and fell above the 95% CI for the continent FN group, although this increase was not considered statistically significant using ANOVA analysis.

Real time rt-PCR was performed for the quantification of FSH-receptor mRNA expression within samples of urinary bladder. In all cases, expression was found to be below the limits of detection of the assay system. To ensure validity of the primers and probes used, they were tested against samples of canine ovary and skin as described in Welle et al. [20]. mRNA for the FSH-receptor was found at very low levels ($3.22E^{-15}$, $n = 2$) in samples of canine skin but was not found in canine ovary.

Carbachol-induced dose dependant contraction of the isolated strips of detrusor muscle from all animals. As in our previous study [9], maximal response was significantly decreased ($P < 0.01$) in neutered compared to entire canines of either gender (Fig. 2). Sensitivity of strips to carbachol, as measured by log EC_{50} values, was also decreased ($P < 0.01$) in neutered compared to entire animals (Table 2). Two-way ANOVA revealed that there was no effect of gender and no interaction between gender and gonadal status. The group of animals identified as suffering from AUI had the lowest maximal contraction of all animals studied, although this was not considered significant using ANOVA.

Statistical analysis revealed a significant positive correlation ($P < 0.001$, $r = 0.607$) between LH- and GnRH-receptor mRNA expression (Fig. 3) and significant negative correlations between the maximal tension produced by detrusor muscle strips and both LH-receptor ($P < 0.001$, $r = -0.671$) and GnRH-

Table 2
Maximum and log EC_{50} values for Carbachol.

	ME ($n = 11$)	MN ($n = 10$)	FE ($n = 10$)	FN ($n = 8$)	FN AUI ($n = 3$)
E_{max}	1.15 ± 0.12	0.49 ± 0.05*	1.27 ± 0.17	0.56 ± 0.06*	0.18 ± 0.03

Maximum (E_{max}) and log EC_{50} values for carbachol in isolated strips of detrusor muscle from entire and neutered, male and female dogs and neutered females identified as suffering from AUI (ME, MN, FE, FN and FN AUI, respectively). Data are expressed as g/mg of wet tissue with results given as mean ± S.E.M. where n: number of animals.

* $P < 0.01$, indicates different from entire of same gender.

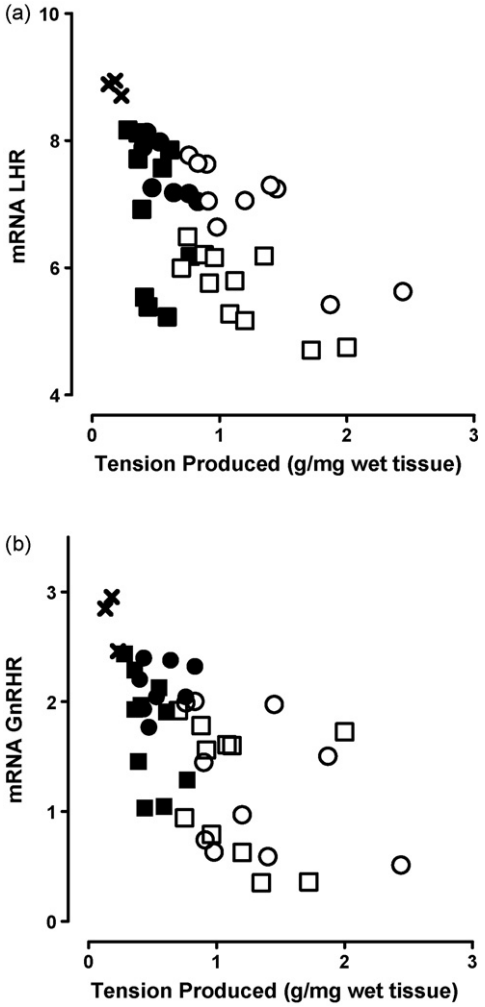

Fig. 4. Correlation between maximal tensions produced by detrusor muscle strips *in vitro* and mRNA expression levels for: (a) LH-receptor ($P < 0.001$, $r = -0.671$) and (b) GnRH-receptor ($P < 0.001$, $r = -0.612$). (□) Male entire, (■) male neuter, (○) female entire, (●) female neuter, and (×) AUI female neuter.

receptor ($P < 0.001$, $r = -0.612$) mRNA expression (Fig. 4a and b, respectively).

Multivariant analysis of the levels of expression of mRNA for both GnRH- or LH-receptor, and the maximum tension produced by detrusor muscle strips indicated no significant effect of age or weight of the animal on the results.

4. Discussion

This is the largest study of the expression levels of the mRNAs for LH- and GnRH-receptors in the canine urinary bladder, and the only study to correlate levels of receptor mRNA expression to bladder contractility (*in vitro*). In addition, although numbers are low, this is the only study to report bladder LH/GnRH-receptor mRNA expression in neutered bitches known to be suffering from AUI.

Bladder contractility is thought to play a significant role in the development of clinical signs of UI [29]. We have previously shown that the maximal contractile response of isolated strips of detrusor muscle to muscarinic and neurogenic stimulation was significantly decreased in neutered compared to entire canines of either gender [9]. We have also demonstrated that sensitivity of the detrusor to muscarinic stimulation is decreased in neutered compared to entire animals of either gender. These results are similar to those reported for studies conducted with tissues collected from women who suffer from UI due to impaired contractility of the bladder [10], a condition known to cause decreased speed and magnitude of detrusor contractions during the emptying phase of micturition. This leads to residual urine retention, a shortened storage phase and predisposes the patient to cystitis [30]. That decreased contractility and sensitivity of the detrusor to muscarinic stimulation in neutered canines may be involved in AUI is supported by the results of this study, looking at animals known to be suffering from AUI, as these had the lowest contractility of all the animals studied. Although impaired bladder contractility has been implicated in UI, the exact mechanisms responsible for its development have not been reported and we hypothesise that the muscarinic receptor effector pathway is involved, its function being altered due to effects in reproductive hormones and the expression of their receptors in the bladder post-neutering/menopause.

It was first suggested that gonadotrophins could influence bladder function in a study which showed that post-menopausal women, who are most likely to suffer from UI, had lower numbers of LH mRNA transcripts and receptors in their bladders than their premenopausal counterparts [25]. As post-menopausal women have a similar hormonal profile to neutered canines, and as both post-menopausal and post-neutering UI are thought to be hormonally related, it follows that a similar aetiology and pathophysiology may link both conditions. Our results clearly show that neutering a canine, regardless of gender, significantly increases levels of mRNA expression for both LH- and GnRH-receptors, and that in general, female animals, regardless of gonadal status, have higher levels of mRNA expression for these receptors than their male counterparts. Although our results, for female canines, are in contrast with those of Tao et al. [25] it should be noted

that in addition to the species difference our study include age matched groups of healthy entire and neutered animals as well as those neutered female canine suffering from AUI, whereas the study by Tao et al. compared women of two distinct age groups, with a number of patients in both groups suffering from UI and genital prolapse, therefore an additional explanation for the difference in the two studies could be an effect of age and mechanical stress on the lower urinary tract. Interestingly, the results of the FN animals in this study known to be suffering from AUI suggest that incontinent neutered bitches may have higher levels of LH-receptor mRNA than their continent counterparts. These findings support the hypothesis that altered gonadotrophins have a role in the pathophysiological mechanism of post-neutering UI as suggested by the efficacy of GnRH analogues in the treatment of canine AUI [13].

In addition to being different from the study reported in humans our results also contradicts with two recent canine studies that reported either no change [24] or a decrease [26] in mRNA expression for these receptors, respectively, in neutered canines. The differences between the three canine studies may again reflect differences in the study populations and conditions. In both of the studies by Reichler et al. [24] and Ponglowhapan et al. [26] a substantially smaller number of animals were used. In addition, the study by Reichler et al. included entire bitches in varying stages of oestrus, thus making comparisons between the groups and studies more complex. Whereas the study by Ponglowhapen et al. looked at relatively acute effects of neutering (24–40 weeks), and thus it is possible as plasma concentrations of FSH and LH continue to increase until week 42 post-neutering [16] and some structural changes may take even longer [31], that there will be significant effects of time post-neutering on the observed mRNA changes.

A further difference between this study and those of Tao et al. and Ponglowhapan et al. is methodological, in that the current study used real time PCR with fresh frozen tissue to quantify mRNA expression levels, whilst the former two studies used in situ hybridisation with formalin fixed, paraffin-embedded tissue. It is known that degradation of target nucleic acids [32,33] and artificial mutations [34] can occur during formalin fixation and paraffin-embedding procedures, which again could have influenced the results, relative to those seen from fresh frozen tissue [35].

The changes in expression of mRNA for LH- and GnRH-receptors observed in our study could support a role for altered expression of GnRH/LH-receptors in the development of AUI in the neutered bitch. Although it is worthy of note that increases in LH- and GnRH-receptor mRNA expression also occurred in the bladders of neutered male canines, which do not typically become incontinent, the magnitude of increase was smaller and the final levels of expression were only marginally above that of entire female canines which also rarely become incontinent. The sex difference in the propensity to develop AUI may also reflect an interaction between post-neutering effects on smooth muscle function and anatomical differences in the urethra of a male canine as has been previously hypothesized [36]. It may be the case however that there is a threshold level of LH- and GnRH-receptor expression, above which UI is more likely to develop. This possibility is supported by the fact that the three animals known to be suffering from AUI had the highest LH- and GnRH-receptor mRNA expression levels observed in this study.

The exact role of the LH-receptor in the urinary bladder has not yet been described. It is known that the plasma concentrations of LH increase in both post-menopausal women and in neutered dogs [16,37], although it is still released in a pulsatile manner. It is also known that this subset of the population is most prone to developing UI. In this study we have shown that neutering causes an increase in mRNA expression levels for the LH-receptor in the canine urinary bladder, and that these expression levels are highest in bitches known to be suffering from AUI. We have also shown that maximal bladder contractility is decreased in neutered animals and is lowest in bitches suffering from AUI and that there is a direct inverse correlation between bladder contractility and mRNA expression levels for LH. It therefore follows that the increase in mRNA for the LH-receptor may be implicated in the decrease in contractility of the detrusor muscle in the canine, either directly or via interactions with another mechanism, possibly involving the muscarinic receptor effector pathway, the primary pathway involved in bladder contraction [38].

The exact role of the GnRH-receptor within the urinary bladder has not been characterised in any species. However, based on a recent study that reported increases in bladder threshold volume following administration of GnRH analogues to neutered continent bitches it has been hypothesized that it may have a role in determining bladder function [12]. This could occur if GnRH-receptor expression modulated the bladders sensitivity to muscarinic stimulation to affect the bladder threshold volume. This hypothesis is supported by the data contained within our study,

where a decrease in *in vitro* detrusor muscle sensitivity to muscarinic stimulation was seen in neutered canines when GnRH-receptor mRNA expression levels were found to be high. Thus, the increase in GnRH-receptor expression could be associated with a decreased sensitivity of the detrusor which would allow further relaxation of the bladder and increased capacity.

Although our study did not identify mRNA for FSH-receptor in the canine bladder two other studies [20,23] have reported its expression within this tissue. The reason for these reported differences studying FSH-receptor mRNA expression, could be methodological, as Ponglowhapan et al. [23] used in situ hybridization whilst our study used real time PCR techniques. Alternatively it could be related to differences in the FSH mRNA sequences used, as our results were similar to those described by Welle et al. [20], who used the same primers and probes and reported expression in canine skin, and inconsistent expression within the canine bladder [20] whilst Ponglowhapan et al. used a different molecular sequence as the basis for their probe. As FSH is known to express multiple isoforms [39] it is a possibility that the primers and probes used in this study and that of Welle et al. [20] were designed against part of the mRNA sequence of an FSH-receptor isoform that is expressed in skin but not in the bladder. As part of the validation of the probe in the current study, in addition to testing the primer and probes against bladder and skin, ovarian tissue was also included as the ovary is a key target organ for the actions of FSH [40]. The ovary, however, was also found to be devoid of significant quantities of the FSH-receptor mRNA expression that could be identified using these primers and probes. Thus, at this point, we are unable to make any definitive conclusions with regard to the effects of neutering on FSH-receptor mRNA expression within the bladder wall.

In conclusion we have shown that neutering a canine, regardless of gender, is associated with an increase in the levels of mRNA for LH- and GnRH-receptors in the canine urinary bladder, and that female animals, regardless of gonadal status have higher LH-/GnRH-receptor mRNA expression levels than males. A further novel observation shown by this study is the positive correlation between increased mRNA expression for LH- and GnRH-receptors and the negative correlation between expression of these receptors and contractility of the detrusor to muscarinic stimulation *in vitro*. It is hypothesized that the changes in mRNA expression for both GnRH- and LH-receptor may have a role to play in the development of post-neutering AUI and this hypothesis is supported by data from a limited number of neutered female canines identified as suffering from AUI which had the highest levels of LH- and GnRH-receptor mRNA expression and the lowest contractility to muscarinic stimulation of all the animals studied.

ABSTRACT

Sexual stimulation induces rapid secretion of cortisol and prolactin (PRL) in stallions. Experiment 1 was designed to determine whether stallions associated location and(or) procedure with previous sexual stimulation in that location. After a control period on d 1, four stallions were exposed to an estrous mare for 5 min on d 2. On d 3, 4, 5, and 6, the same procedure was followed with no mare present. Concentrations of PRL and cortisol increased ($P < .05$) after mare exposure on d 2 but did not vary ($P > .05$) on d 1, 3, 4, 5, or 6. In Exp. 2, six stallions were used to determine the short-term effects of 1) sexual stimulation, 2) acute physical exercise, 3) restraint via a twitch (twitching), 4) epinephrine administration, and 5) no stimulation on plasma concentrations of PRL and cortisol. Stallions received one treatment per day separated by 2 d of no treatment. Concentrations of cortisol increased ($P < .05$) within 10 min after sexual stimulation, exercise, twitching, and epinephrine administration but not during control bleedings. Concentrations of PRL increased ($P < .05$) immediately after sexual stimulation, exercise, and twitching but not after epinephrine administration or during control bleeding. In Exp. 3, the same five treatments were administered to six geldings. Concentrations of cortisol increased ($P < .05$) after epinephrine administration, exercise, and twitching but not after sexual stimulation or during control bleedings. Concentrations of PRL increased ($P < .05$) after exercise and sexual stimulation. It is concluded that 1) a single episode of sexual excitement in stallions does not lead to a memory-mediated rise in either cortisol or PRL, 2) in stallions, cortisol and PRL are secreted in response to sexual stimulation, exercise, and twitching, whereas only cortisol is secreted in response to epinephrine administration, and 3) in geldings, PRL is secreted in response to exercise, and cortisol is released in response to epinephrine administration, exercise, and twitching.

Key Words: Stallions, Cortisol, Prolactin, Stress, Sexual Behavior

J. Anim. Sci. 1991. 69:2556–2562

Introduction

Concentrations of cortisol in horses increase after exercise (Snow and Munro, 1975; Dybdal et al., 1980; Snow et al., 1982; Church et al., 1987; Hower and Wickler, 1989), during isolation stress (Alexander et al., 1988), after induction of hypoglycemia and after surgery (James et al., 1970), after restraint via a twitch (Thompson et al., 1988), and after sexual activity (Tamanini et al., 1983; Rabb et al., 1989).

Prolactin (PRL) concentrations also increase after various stressful stimuli in rats (Neill, 1970; Euker et al., 1975; Dohler et al., 1977) and man (Noel et al., 1972). Thompson

et al. (1988) found no effect of restraint via a twitch on PRL secretion in ovariectomized pony mares although ketamine administration briefly increased concentrations of PRL. Sexual stimulation increases PRL secretion in rats (Kamel et al., 1975, 1977; Kamel and Frankel, 1978) and bulls (Convey et al., 1971), as well as in stallions (Rabb et al., 1989).

Rabb et al. (1989) reported that stallions that had previously been exposed to sexual stimulation had increases in cortisol secretion and, to a lesser degree, PRL secretion in the absence of any visual or physical contact with mares. The authors suggested that the sound of other stallions being stimulated was sufficient to cause a memory-mediated rise in cortisol and PRL secretion.

The experiments described herein were designed 1) to determine whether stallions exhibited an increase in cortisol and(or) PRL secretion when returned to the site of a previous sexual encounter and, if so, to determine how long such a response would persist, 2) to compare the cortisol and PRL responses in stallions after sexual excitement to those occurring after various physical and chemical stimuli, and 3) to determine whether the responses to these stimuli in stallions were dependent on the presence of the testes.

Materials and Methods

Experiment 1. Four lighthorse stallions aged 6 to 14 yr were used. All stallions were sexually experienced and were given at least 7 d of sexual rest before the onset of the experiment. Stallions were housed in outdoor lots and were fed sufficient hay and grain to maintain good body condition. At approximately 0700 on the mornings of treatment, each stallion was fitted with an 18-gauge, polyethylene jugular catheter that was flushed with heparinized .15 *M* saline. Stallions were kept loosely tethered in their lots and had ad libitum access to hay and water.

Beginning at approximately 0800 on d 1, 3, 4, 5, and 6, two 5-ml blood samples were drawn via the catheter 10 min apart (–10 and 0 min) and were placed in heparinized tubes. Immediately after the 0-min sample, each stallion was led to a specified site along the fence of his lot and held there for 5 min. On d 2, the same procedure was followed except that an estrous mare was also brought to the site (across the fence) such that the stallion could make visual and limited physical contact for a total of 5 min. On all days, additional blood samples were drawn at 10, 20, and 30 min after time 0.

Experiment 2. Six sexually experienced lighthorse stallions aged 6 to 14 yr were managed as described for Exp. 1. Three of these stallions had been used in Exp. 1. After at least 7 d of sexual rest, all stallions were exposed to each of five treatments: 1) sexual stimulation (5-min exposure to an estrous mare), 2) acute physical exercise (running for 5 min), 3) restraint via a twitch (twitching; 5 min), 4) epinephrine[5] administration (3 mg i.v.), and 5) no stimulation (control). Stallions received one treatment per day on five separate days, with 2 d of sexual rest between treatments (based on results of Exp. 1). The order of treatments for each stallion was unique and was randomly selected from the 120 possible combinations. Also, stallions were started on treatment on a staggered schedule such that only two stallions were treated on any given day.

Blood sampling and other procedures were the same as those described for Exp. 1. Immediately after the 0-min blood sample, the appropriate treatment was administered. Subsequent samples were taken at 10, 20, and 30 min after time 0. To minimize the amount of activity seen and heard by a stallion on his treatment day, the two treated stallions for each day were housed approximately 100 m apart.

Experiment 3. Six long-term (> 1 yr) geldings aged 5 to 15 yr and of unknown sexual experience were exposed to the same five treatments described for Exp. 2. Geldings were managed in the same manner as the stallions. Each gelding also received a unique sequence of treatments with 2 d of rest between treatments. Procedures and frequency for blood collection were identical to those described for Exp. 2.

Radioimmunoassay and Statistical Analyses. All blood samples were kept on ice and were centrifuged within 1 h after collection. Heparinized plasma was harvested and stored

at −15°C. Concentrations of cortisol in plasma were measured by RIA as described previously (Thompson et al., 1988). Sensitivity of the cortisol assay was 37 pg/tube, and inter- and intra-assay CV were 12 and 6%, respectively. Concentrations of PRL in plasma were measured by double-antibody RIA similar to that described by Thompson et al. (1986). Antiserum (R4PRL) generated in a rabbit against porcine PRL (USDA-pPRL-B-1) was diluted 1:15,000 and was used at 200 μl/tube. Highly purified equine PRL (AFP-2451B[6]) was radioiodinated by the chloramine-T method and was isolated on Sephadex G-25. Inhibition curves in the assay generated with serial dilutions of equine plasma and pituitary homogenates were all parallel to those produced by purified equine prolactin. Cross-reactivities in the prolactin assay of equine LH, equine FSH, equine thyrotropin-stimulating hormone, porcine and canine growth hormone, synthetic adrenocorticotropic hormone and pregnant mare's serum gonadotropin were < .145, < .07, .53, .19, .06, < .0001, and < .03%, respectively. Moreover, fractionation of a pool of pituitary extracts via PAGE yielded a single peak of immunoreactivity coincident with radiolabeled equine prolactin. For 20 randomly selected samples of plasma, regression of PRL estimates in this assay with estimates from our previous assay (Thompson et al., 1986) resulted in a correlation coefficient of .95. Sensitivity of the PRL assay averaged .04 ng. Intra- and interassay CV averaged 7 and 12%, respectively. For each hormone, all samples from a given stallion were included in a single assay.

In all experiments, data for each hormone were analyzed by split-plot ANOVA with stallions as the random effect (Steel and Torrie, 1980). Fixed main effects were days and sampling times in Exp. 1 and treatments and sampling times in Exp. 2 and 3. Due to heterogeneity of variances, data were also analyzed after log transformation, but this was found not to affect the overall results. Before analysis, data from each stallion were placed on a percentage of pretreatment (average of −10 and 0 min samples) basis to eliminate pretreatment variation among stallions; only posttreatment samples (10, 20, and 30 min) were used in the ANOVA. The lsd test was used to determine whether treatment means differed from 100% (Steel and Torrie, 1980).

Results

Experiment 1. Concentrations of cortisol and PRL in plasma of stallions increased ($P < .05$) only on the day of exposure to an estrous mare (d 2; Figure 1). This increase occurred within 10 min of PRL, which remained elevated through 30 min. Concentrations of cortisol increased by 30 min. On the pre-exposure (d 1) and all post-exposure days (d 3, 4, 5, and 6), none of the means for either cortisol or PRL differed from 100%.

Experiment 2. Concentrations of cortisol in plasma of stallions during the control period did not vary ($P > .05$) relative to pretreatment (Figure 2). Concentrations of cortisol for all other treatments increased ($P < .05$) rapidly after the onset of treatment. These concentra-

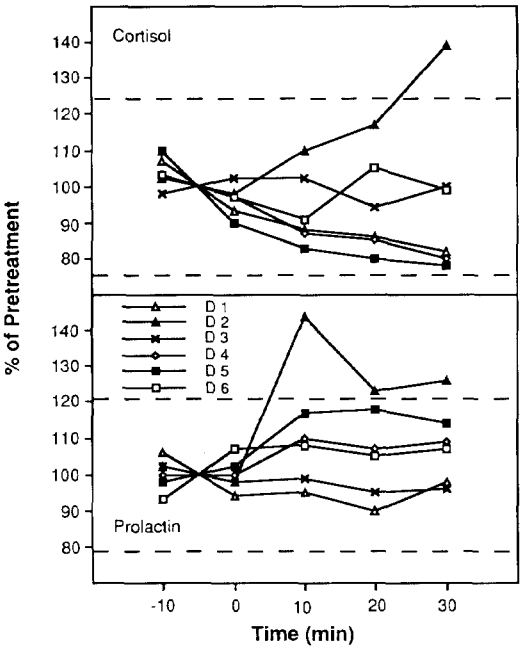

Figure 1. Concentrations of cortisol and prolactin in plasma of stallions exposed to an estrous mare for 5 min on d 2 and returned to the site of exposure on d 3, 4, 5, and 6. Day 1 was a control period (no mare present). Data are expressed as percentage of pretreatment. Horizontal dashed lines bracketing 100% indicate ± the lsd ($P < .05$). Pooled SE for cortisol and prolactin were 8.6 and 7.4%, respectively. Actual pretreatment concentrations of cortisol and prolactin averaged 28.4 and 9.0 ng/ml, respectively.

tions remained elevated ($P < .05$) through 30 min for all treatments.

Concentrations of PRL increased ($P < .05$) in stallions in response to sexual stimulation and exercise (Figure 2) at 10 min and remained elevated through 30 min. Concentrations of PRL increased ($P < .05$) in response to twitching only at 10 and 30 min. Means for the control period and epinephrine administration did not vary ($P > .05$) relative to time 0.

Experiment 3. Concentrations of cortisol in plasma of geldings did not vary ($P > .05$) relative to pretreatment for the control period or during sexual stimulation. Concentrations of cortisol increased ($P < .05$) within 10 min after the onset of exercise and within 20 min after epinephrine administration and twitching (Figure 3) and remained elevated through 30 min.

Concentrations of PRL in plasma of geldings did not vary ($P < .05$) relative to pretreatment during the control period or after epinephrine administration or twitching (Figure 3). Concentrations of PRL increased ($P < .05$) an average of 3.5-fold within 10 min after exercise and remained elevated through 30 min. There was a minor (50%) increase ($P < .05$) in concentrations of PRL in plasma of geldings after exposure to an estrous mare.

Discussion

The results of Exp. 1 and 2 were similar to those reported by Rabb et al. (1989) for concentrations of cortisol and PRL in stallions after sexual stimulation with or without ejaculation. In our experiments and in that of Rabb et al. (1989), concentrations of PRL increased rapidly after sexual stimulation and then declined. Similar results have been reported for the rat (Kamel et al., 1975, 1977; Kamel and Frankel, 1978) and bull (Convey et al., 1971), in which concentrations of PRL peaked rapidly

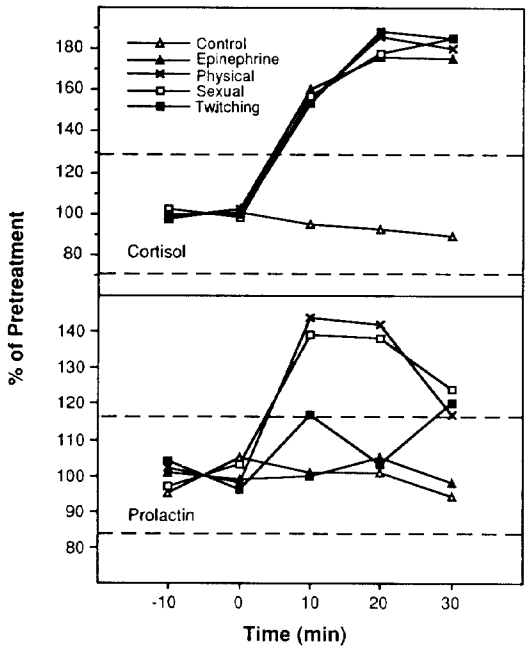

Figure 2. Concentrations of cortisol and prolactin in plasma of stallions exposed to sexual stimulation, physical exercise, restraint via a twitch, epinephrine administration, or no stimulation (control) beginning immediately after time 0. Data are expressed as percentage of pretreatment. Horizontal dashed lines bracketing 100% indicate ± the lsd ($P < .05$). Pooled SE for cortisol and prolactin were 10.4 and 5.7%, respectively. Actual pretreatment concentrations of cortisol and prolactin averaged 18.3 and 5.9 ng/ml, respectively.

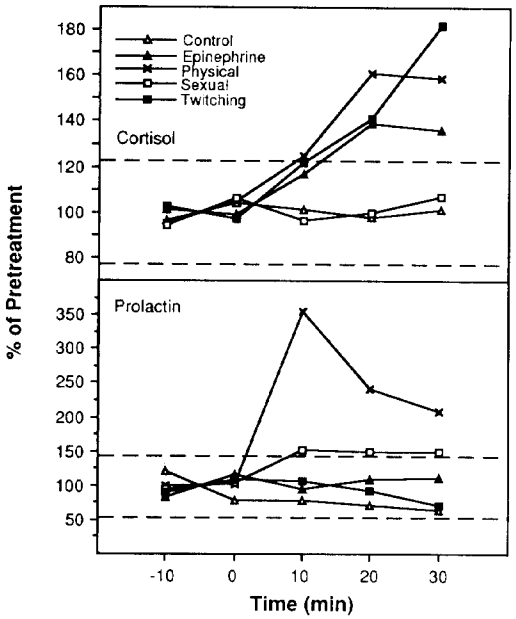

Figure 3. Concentrations of cortisol and prolactin in plasma of geldings exposed to sexual stimulation, physical exercise, restraint via a twitch, epinephrine administration, or no stimulation (control) beginning immediately after time 0. Data are expressed as percentage of pretreatment. Horizontal dashed lines bracketing 100% indicate ± the lsd ($P < .05$). Pooled SE for cortisol and prolactin were 7.7 and 16.4%, respectively. Actual pretreatment concentrations of cortisol and prolactin averaged 21.6 and 1.8 ng/ml, respectively.

after mating. However, it has been reported that concentrations of PRL vary considerably in humans after sexual intercourse (Noel et al., 1972; Stearns et al., 1973).

There was no increase in secretion of cortisol or PRL on the days after return of the stallions to the site of their previous sexual stimulation. These data support the contention of Rabb et al. (1989) that the cortisol and PRL responses during control periods in their stallions previously exposed to sexual stimulation were not induced by the location of the control treatments, but rather by the sounds of other stallions being sexually stimulated at the same time. We also concluded from Exp. 1 that 2 d of rest between treatments would be sufficient to avoid carry-over effects from one treatment to the next, assuming the sounds and other potential stimuli were absent.

Concentrations of cortisol in stallions after sexual stimulation in Exp. 1 increased at a slower rate than those in Exp. 2 or those reported previously (Tamanini et al., 1983; Rabb et al., 1989). In the latter three experiments, concentrations of cortisol increased within 10 min or less relative to treatment. In Exp. 1, concentrations of cortisol did not rise until 30 min after treatment. The reason for this delayed response is not known.

It is likely that a general stimulation (discharge) of the sympathetic nervous system is the common event mediating the cortisol response to physical exercise, twitching, and other similar physical stimuli. Because sexual stimulation in stallions usually involves physical activity, the cortisol rise in response to sexual excitement might be attributed solely to this physical component. However, Rabb et al. (1989) reported that previously exposed stallions seem to be able to respond to the sounds of sexual activity with a cortisol rise in the absence of any noticeable physical activity, indicating a strictly psychic mediation (conditioned response). As expected, geldings showed only casual interest in mares during the exposure period. Because there was no sexual excitement, there was no associated physical activity and apparently no psychic stimulation, given the lack of a cortisol response.

Although there was a significant PRL response to sexual stimulation in geldings, the response was minimal and was present in only three of the six animals. Whether or not this increase was truly due to mare exposure needs to be studied further. Given that there was no simultaneous response in concentrations of cortisol, we believe that the PRL response may be of little physiologic significance. The only other treatment in which geldings differed from stallions was twitching, which itself was variable among stallions. If the cortisol and PRL responses observed in these experiments are mediated through discharge of the sympathetic nervous system in both stallions and geldings, these responses would not be expected to be gonadally dependent. However, it is possible that stallions are generally more excitable because of the presence of testicular androgens and estrogens in their blood, and thus may respond to stimuli of intermediate intensity, such as twitching, more readily than geldings.

In stallions as well as geldings, bolus administration of epinephrine resulted in a rapid increase in concentrations of cortisol in all animals. James et al. (1970) injected similar amounts of epinephrine into two ponies over a 2- to 5-min period and found no significant increase in concentrations of cortisol, even though lacrimation, profuse sweating, trembling, and rapid respiration were observed. The slower rate of administration used by James et al. (1970) apparently accounted for the lack of cortisol rise in their ponies. The lack of a PRL response to epinephrine injection indicates that the PRL responses to other forms of physical and sexual stimuli are via neural pathways that are not directly affected by catecholamines or cortisol. In contrast, the epinephrine effect on cortisol secretion may indicate an interaction of epinephrine with nervous pathways leading to secretion of corticotropin-releasing hormone and(or) adrenocorticotropic hormone.

Physical activity for 5 min caused a rapid increase in concentrations of cortisol in both stallions and geldings. These results are in agreement with others concerning concentrations of cortisol in horses after exercise of various intensities and durations (Snow and Munro, 1975; Dybdal et al., 1980; Snow et al., 1982; Church et al., 1987; Hower and Wickler, 1989). It was reported that physical training does not affect this increase in cortisol (Church et al., 1987), although trained horses do have a more rapid recovery rate of concentrations of cortisol, decreasing back to normal with 30 min (Hower and Wickler, 1989). In Exp. 2 and

Downloaded from jas.fass.org by guest on July 10, 2011

3, all stallions and geldings were untrained, which likely accounts for the continued elevation of concentrations of cortisol at 30 min after treatment.

Restraint via a twitch caused a rapid increase in concentrations of cortisol both in stallions and geldings. Thompson et al. (1988) reported a similar increase in cortisol secretion in ovariectomized pony mares after twitching, with peak concentrations occurring within 20 min. In contrast to ovariectomized pony mares and geldings, stallions also exhibited a transient increase in plasma concentrations of PRL after twitching. Given the diversity in these three experiments and the variability in response within Exp. 2, it is apparent that the PRL response to twitching is not as consistent as the cortisol response.

The increased secretion of PRL in stallions after sexual excitement has been speculated as being part of a generalized stress response rather than a result of any specific reproductive function (Rabb et al., 1989). The results of this study are consistent with this idea, given that similar PRL and cortisol responses occurred in stallions and geldings after various types of stimuli. However, the fact that twitching produced varied results indicates that all apparently stressful stimuli may not have the same impact on PRL secretion. Because the role of PRL in the horse has yet to be defined, the reason for its secretion in response to these stimuli is unknown.

Implications

These experiments provide further evidence that cortisol and prolactin are secreted in response to various sexual and physical stimuli in stallions and geldings. The cortisol and prolactin responses to acute exercise do not seem to be gonadally dependent, because they occur similarly in stallions and geldings. The cortisol and prolactin responses to sexual stimulation in stallions do not differ from those after acute exercise, indicating that the physical component of sexual excitement may be the main factor responsible for their occurrence.

Population Dynamics and Fertility Control of Feral Horses

GAIL H. COLLINS,[1] *U.S. Fish and Wildlife Service, Sheldon-Hart Mountain National Wildlife Refuge Complex, Lakeview, OR 97630, USA*
JOHN W. KASBOHM, *U.S. Fish and Wildlife Service, Sheldon-Hart Mountain National Wildlife Refuge Complex, Lakeview, OR 97630, USA*

ABSTRACT The management of free-roaming, feral horse (*Equus caballus*) populations in the western United States is a contentious and challenging issue. Between 2008 and 2014, 1,873 individual horses from a closed population in the northern Great Basin, USA were captured, uniquely marked, and were either removed for private adoption or had permanent fertility control treatments (i.e., vasectomy or ovariectomy) applied prior to release. We derived the annual population size, growth rate, and the number of horses by sex and age by using the horse's estimated age at first capture to infer its age during each year it was part of the population. Estimates of population size from 2 aerial survey techniques averaged within 5.3%–9.6% of derived population estimates. The overall survival (i.e., recapture) rate for individual horses was 88% for individuals released back into the population between 2009 and 2012. Treated horses maintained group associations and there were no differences between survival rates for released females or males that received fertility control treatment, compared to animals released without treatment. The application of combined fertility control efforts resulted in a decline in the population-level annual foaling rate from >20% to <4% within 4 years. Maintaining a proportion of a population as permanently non-reproducing has the potential to safely maintain free-roaming horse herds at desired management levels. © 2016 The Wildlife Society.

KEY WORDS *Equus caballus*, feral horse, fertility control, foaling, ovariectomy, population dynamics, vasectomy.

Management of free-roaming, feral horses (*Equus caballus*) in the western United States is an increasingly controversial and contentious issue. The species is viewed as a symbol of freedom and an icon of the American West, but horses also are a non-native, feral grazer that present significant land management challenges. Unmanaged or poorly managed non-native grazers, including horses, can have substantial impacts on ecosystem integrity, influencing a wide array of native flora (Smith 1986, Levin et al. 2002, Zalba and Cozzani 2004, Beever et al. 2008, Davies et al. 2014), fauna (Beever 2003, Beever and Brussard 2004, Beever and Herrick 2006, Hall et al. 2016, Gooch et al. 2017), and ecosystem processes (Beever and Brussard 2000, Zeigenfuss et al. 2014). On lands managed by the Bureau of Land Management in the western states alone, there are an estimated >67,000 free-roaming horses and burros (*Equus asinus*) occupying 12.8 million ha, more than twice the maximum management level that can exist in balance with other public rangeland resources and uses (Bureau of Land Management 2016*a*).

Free-roaming female horses typically have their first foals at 2–3 years of age, often produce foals in consecutive years, and remain reproductively active throughout their lives with only a small reduction in foaling rates in the oldest age classes (Speelman et al. 1944, Berger 1986, Siniff et al. 1986, Wolfe et al. 1989, Garrott et al. 1991). In addition, mortality rates for free-roaming horses are low as or lower than other similarly sized, native mammals (Berger 1986); annual survival estimates for adult horses have ranged from 70–80% (Wolfe 1980) to 95% and higher (National Research Council 1980, Berger 1986, Garrott and Taylor 1990). The result is that free-roaming horse populations can grow at annual rates of 15–20% or more per year (Eberhardt et al. 1982, Berger 1986, Garrott and Taylor 1990) and it is expected that most populations approach this biological potential because current management generally ensures that horses are not resource- or self-limited (National Research Council 2013).

Western land managers have traditionally relied on the practice of capture, removal, and public adoption to manage free-roaming horse abundance. This process is costly and unsustainable because the number of adopted animals represent only a fraction of animals removed, which has resulted in almost as many horses now held for the remainder of their lives in long-term, federally subsidized private pastures as there are on the range (Garrott and Oli 2013, Bureau of Land Management 2016*a*). Consequently, despite previously aggressive programs to control the number of horses on public rangelands, current management strategies have not been able to reduce free-roaming horse populations to target levels (National Research Council 2013). For a segment of the public, neither capturing and removing horses nor letting horses perish on the range as a result of limited resources is

Received: 25 August 2015; Accepted: 14 October 2016

[1]*E-mail: gail_collins@fws.gov*

acceptable. Methods to control population growth (e.g., fertility control, contraception) may reduce the need for intensive and controversial removals while ensuring that free-roaming horse populations do not become self-limiting (National Research Council 2013). Controlling population growth would also provide significant cost-savings to the American taxpayer (Bartholow 2007, de Seve and Griffin 2013) by affecting the ability to attain free-roaming horse management goals (National Research Council 2013).

Fertility control has been an attractive alternative to managing wildlife and other animal populations that have become overabundant (Ransom et al. 2014*b*), including free-roaming horses, white-tailed deer (*Odocoileus virginianus*), and elk (*Cervus canadensis*; Hobbs et al. 2000, Ransom et al. 2010). Contraception that persists for the lifetime of the animal may be the most efficient method for maintaining a population at target densities once an adequate number of animals have been sterilized (Hobbs et al. 2000). However, little empirical data are available on how such efforts affect population-level rates of change (Ransom et al. 2014*b*) or have demonstrated meaningful reductions in population growth rates in the field (Hobbs et al. 2000). Although a wide variety of fertility control agents have been and are being investigated for free-roaming horses (Bureau of Land Management 2016*b*), many of the management tools examined thus far are costly or impractical for large-scale use (Ransom et al. 2014*a*). In addition, managers are generally constrained by a lack of data including scientifically defensible horse population estimates, population growth rates, demographics, and subsequent effects of these proposed management actions (National Research Council 2013). One contraceptive technique, permanent sterilization of males via vasectomy, has had limited field application and previously targeted only socially dominant individuals (Eagle et al. 1993); although it has been recognized that the strategy of targeting only dominant males may not be successful in limiting population growth (Garrott and Siniff 1992, Bowling and Touchberry 2001). A second technique, targeting female horses for contraceptive control via permanent sterilization (i.e., ovariectomy) has not been tested within free-roaming horse populations to date.

We report on an 8-year study of the population dynamics of a free-roaming, feral horse herd in the northern Great Basin, USA. Our objectives were to evaluate the effectiveness of 2 permanent sterilization techniques used to control population growth while targeting individuals of both sexes regardless of social status.

STUDY AREA

Sheldon National Wildlife Refuge (Refuge), managed by the United States Fish and Wildlife Service, consisted of approximately 234,703 ha in northwest Nevada, USA, in the northern Great Basin. The Refuge was established in 1936 for the conservation of American pronghorn (*Antilocapra americana*) and other native sagebrush-obligate species, including greater sage-grouse (*Centrocercus urophasianus*). Elevations ranged from 1,326 m to 2,183 m. Recent summer temperatures ranged from 0°C to 34°C and winter temperatures between −29°C and 14°C; annual precipitation rarely amounted to more than 30 cm. Dominant vegetation consisted of shrubs, primarily sagebrush (*Artemisia* spp.) and associated sagebrush-steppe habitats. Scattered open woodlands consisting of western juniper (*Juniper occidentalis*) or curl-leaf mountain mahogany (*Cercocarpus ledifolius*) occupied ridgelines and some slopes. Aspen (*Populus* spp.) and willows (*Salix* spp.) were found in dispersed snowpockets and in areas of persistent water.

The feral horse population occupying Sheldon National Wildlife Refuge dated back to prior to the establishment of the Refuge as privately owned animals escaped or were released from ranches and grazing allotments (U.S. Fish and Wildlife Service 2013). During the early 1990s, the horse population averaged 200–300 animals as a result of a proactive population control (removal) program; however, without continued active management, the population substantially increased by the mid-to-late 2000s necessitating management action. Since the early 2000s, feral horses were reported to affect the Refuge's natural resources and native wildlife (Barnett 2002, Davies et al. 2014, Zeigenfuss et al. 2014, Gooch et al. 2017) and were targeted for removal in 2013–2014 (U.S. Fish and Wildlife Service 2013). Small numbers of feral burros also occurred on the Refuge but were not included in this study. The area surrounding the Refuge was predominantly federal land administered by the Bureau of Land Management, and included areas designated as wild horse Herd Management Areas (HMAs) and Herd Areas (HAs); recent surveys estimated over 3,200 horses occupying the surrounding areas (Lubow 2015). A fence along the exterior boundary of the Refuge geographically restricted the movement of livestock, horses, and burros between the Refuge and adjacent lands.

METHODS

Between 2008 and 2014, each fall we used a helicopter to herd feral horses into a trap corral and then transported them by trailer to an on-site facility for handling (U.S. Government Accountability Office 2008). An equine veterinarian estimated the age of each captured horse using teeth characteristics (e.g., eruption date, rate of growth, tooth wear; McMullan 1983). Accurately aging animals by teeth characteristics can be challenging because of individual rates of tooth growth and wear; therefore, the same person aged all horses to ensure consistency in estimates over the duration of the study. We determined the sex of each horse, and paired females with their dependent foals. From 2008 to 2012, we removed approximately 10–20% of the total population each year (predominantly younger horses estimated at <5 yr) from the Refuge and transported them to contractors for private adoption; no removals occurred in 2007. We treated the majority of the remaining captured animals (i.e., those not transported for adoption) with permanent fertility control and released them back at the site of capture. Horses established as previously captured and marked (see below) were identified and recorded, and assessed for removal or re-release back onto the Refuge (prior to 2013). We surgically vasectomized (2008–2009) or chemically epididymectomized (2010–2011; Scully et al. 2015) males and surgically ovariectomized females via colpotomy (2009–2011; McKinnon et al. 1991, Hooper et al.

1993, Auer and Stick 1999). Costs associated with treatments ranged from approximately $125/horse for vasectomies to $150/horse for ovariectomies, and included veterinarian time and veterinary supplies (L. G. Pielstick, HCVC, personal communication).

Veterinarians experienced in handling domestic and non-domestic horses performed all procedures. All procedures followed taxon-specific guidelines approved by the American Society of Mammalogists (Sikes et al. 2016), consistent with recommendations for wild taxa (Sikes et al. 2012). In addition, we contracted with an independent veterinarian to provide protocol and program review and animal welfare oversight during all phases and for the duration of the study. We held and observed treated horses in captivity on average 3–8 days before release, as per veterinarian recommendations, and the losses attributed to treatment complications pre-release was 2% ($n = 8$). We implanted all horses with a uniquely identifying microchip in a passive integrated transponder (PIT) tag. We injected the microchip into the nuchal ligament along the base of the horse's mane to reduce the potential for tag migration (Stein et al. 2003); tag retention was 100%. We also marked individuals that received fertility control treatments with a visible freeze-brand signifying treatment type. In 2013 and 2014, all remaining horses in the population were targeted for removal and transportation to contractors for private adoption, including those which had been previously captured and released; approximately half of the animals were removed in 2013 ($n = 415$) and the remainder in 2014 ($n = 397$). As of fall 2015, an estimated <30 horses remained on the Refuge.

We compared 2 aerial survey methods used to monitor temporal trends in the feral horse population. Each July between 2007 and 2014, as part of routine wildlife composition surveys, a pilot and 2 experienced observers made uncorrected direct (i.e., raw) counts of horses from a helicopter flying linear transects at approximately 91 m above ground level (AGL) and 0.4-km spacing, dependent upon visibility, terrain, and habitat. We recorded the global positioning system (GPS) location of and the number of individuals in each group of horses, classified each animal as an adult or foal (<1 yr), and noted the number of freeze-branded individuals present by treatment type. We used the July helicopter survey data to evaluate differences in group size over time and group association of treated individuals, and to calculate observed foaling rates (foals:100 adults). We used foals:100 adults rather than foals:100 females because the sexes are not distinguishable from a distance (i.e., during aerial surveys), and to be comparable to foaling rates commonly derived from aerial survey estimates for adjacent and other free-ranging horse populations.

In addition to annual helicopter surveys, we also surveyed horses on the Refuge in June 2008, 2010–2012, and 2014 as part of a larger, interagency landscape-level effort, which included surveying 14 surrounding wild horse HMAs and HAs administered by the Bureau of Land Management. This double-observer count technique, detailed by Ransom (2012) and which includes an analysis of detection probabilities, used a fixed-wing aircraft (Cessna 185, 206, or 210) to fly parallel transects spaced 2.4 km apart at approximately 152 m AGL at approximately 100–140 knots. A pilot and 3 observers independently recorded GPS locations of horse groups when sighted, number of horses in each group, and age classification (foal vs. adult; 2010, 2011, and 2014 only). We used the observed June foaling rate (i.e., foals:100 adults) obtained from fixed-wing surveys to compare annual rates across populations within the larger landscape.

Because the recapture rate for individuals was 88% for the entire study period (i.e., 88% of individual horses captured, marked, and released back onto the study area were physically recaptured ≥1 yr later), we assumed this to be an essentially closed population, with minimal exchange of horses moving between the fenced study area and surrounding lands in any given year. This was further corroborated by data collected between 2009 and 2012 from horses marked with collars outfitted with GPS receivers (Collins et al. 2014), all of whom remained entirely within the study area (G. H. Collins, U.S. Fish and Wildlife Service, unpublished data). We derived the annual population size and number of horses by sex (sex ratio) and age class (foal [<1 yr], 1-yr-old, 2-yr-old, adult [≥3 yr]) each year by using the horse's estimated age at first capture to infer its age during each year it was part of the population (Table 1). We assumed all horses ≥3 years

Table 1. Number of feral horses by year and reproductive status (treated vs. untreated) derived by using the horse's estimated age at first capture to infer its age during each year it was part of the population, Sheldon National Wildlife Refuge, Nevada, USA, 2007–2014.

Age/sex class	2007	2008	2009	2010	2011	2012	2013	2014

[a] Fixed-wing survey with corrected population estimate using sighting probabilities; no fixed-wing surveys conducted in 2007, 2009, or 2013. Individual survey results can be found in Lubow (2009), Lubow et al. (2010), Lubow (2011), Manning (2013), and Lubow (2015).
[b] Helicopter survey with uncorrected direct (i.e., raw) count.
[c] Derived by using the horse's estimated age at first capture to infer its age during each year it was part of the population.
[d] From derived population estimate. Declining values for 2008–2014 represent the combined result of removals and fertility control treatments.

old to be capable of reproducing (Garrott and Taylor 1990) unless treated with fertility control.

Foal mortality in free-roaming horse populations is highest during the first 1–2 months of life (Welsh 1975, Boyd 1979, Berger 1986, Turner and Morrison 2001). As such, we defined foal recruitment as foals that survived to October each year. We derived the actual number of foals and actual foaling rate (foals/adults) for each year. We calculated estimated annual foal recruitment as the difference between observed (Jul) and actual (Oct) foaling rates. In 2007 and 2008, prior to fertility control treatments, the derived ratio of recruited foals to adult females averaged 45% (47.9% and 43.2%, respectively), that is, an average of 45% of all potentially reproductive adult females (≥3 yr) recruited foals each year. Using that average, for each year, we estimated the number of recruited foals that would have been expected had no fertility control treatments been applied (adult females × 0.45) and the expected foaling rate without treatment (expected foals/adults).

To infer the relative effectiveness of each treatment type, we calculated the expected number of recruited foals if only females were treated ([adult F × 0.45] − [treated F × 0.45]) and divided by the number of adults to calculate the foaling rate considering treated females only for each year. We calculated the fecundity of reproductive females exposed to treated males present in the population as the derived ratio of number of foals to untreated adult females. We performed statistical analyses following Wilkinson (1990). We used Pearson's chi-square to test for differences in survival rates (i.e., recapture rates) between treated and untreated horses. We used multiple regression analysis of variance to determine whether 1) the number of treated males or females was correlated with group size as observed during aerial surveys; and 2) the number of foals was correlated with group size, the number of treated males, or number of treated females; $P \leq 0.05$ was considered statistically significant.

RESULTS

Between 2008 and 2014, we captured 1,873 individual feral horses. The population occupying the Refuge was estimated to have reached a high of around 1,400 animals in 2008 and, with the exception of 2007, both aerial survey techniques used to estimate the size of the feral horse population were in close agreement with derived estimates of population size (Table 2). The population's adult sex ratio averaged from 127.2 males:100 females (2007–2012) to 172.2 males:100 females (2013–2014; Table 1). For recruited foals, the sex ratio averaged 90.2 males:100 females for 2007–2014 (range = 68.2–120.0 M:100 F).

Estimated ages of captured horses ranged from dependent foals at 2–3 months old to 30 years old for males and 26 years old for females. Estimated ages of untreated females with dependent foals ranged from 2–22 years old, with foal recruitment peaking for females at 3–11 years old (79.1%; Fig. 1). Estimated ages of fertility control treated males ranged from 1–27 years old (83% were ≥7 yr old) and for fertility control treated females 2–26 years old (84% were ≥7 yr old). Recapture rates (i.e., survival rates) for individual horses were 85.3% for released females ($n = 150$) and 89.2% ($n = 278$) for released males across the period of study. Survival rates for released females that received fertility control treatment (85.1%, $n = 114$) did not differ from females that were released without treatment (86.1%, $n = 36$; $\chi^2 = 0.023$, $P = 0.880$). Also, survival rates for released males that received fertility control treatment (89.2%, $n = 268$) did

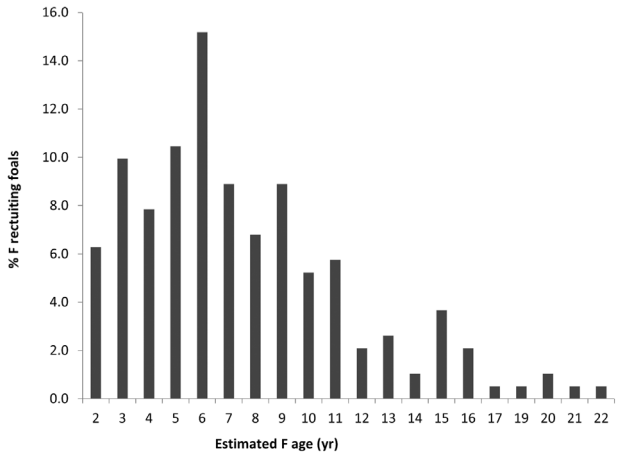

Figure 1. Estimated ages of untreated female feral horses recruiting foals (accompanied by dependent foals in the fall each year), Sheldon National Wildlife Refuge, Nevada, USA, 2008–2014.

not differ from those that were released untreated (90.0%, $n = 10$; $\chi^2 = 0.007$, $P = 0.935$). Of the treatments applied to released males, 51% received surgical vasectomies ($n = 137$) and 47% were chemically epididymectomized ($n = 126$); we also recaptured 5 males that were surgically castrated and released prior to this study (~2005). The percent of treated individuals in the population ranged from 7.4–35.3% each year, with 8.0–30.3% for females and 19.3–47.8% for males (Table 1).

Based on helicopter surveys, horse group sizes in July did not differ for 2008–2011, averaging 9.9 individuals/group (range = 1–115 ± 13.9 [SD], $n = 446$ groups). Group sizes were smaller in 2012–2013 ($\bar{x} = 6.2$ horses/group, range = 1–63 ± 7.6, $n = 291$ groups). We were able to determine the sex composition for 61% of the groups we observed during helicopter survey efforts ($n = 737$ groups) using the combined presence of foals and marked individuals. Of those, 48.4% were mixed-sex groups (≥1 M and ≥1 F; $n = 357$) and 13.1% were solitary animals ($n = 97$); the sex composition of the remaining groups ($n = 283$) could not be determined (i.e., no foals present or combination of marked individuals). Of the solitary animals documented, 23.7% were treated males ($n = 23$ observations); there were no observations of solitary treated females. Because they were not visibly marked, it is unknown how many of the remaining solitary individuals were untreated males versus untreated females. However, during captures in 2013 and 2014, the number of horses captured alone was predominantly untreated males; therefore, it is reasonable to assume that the majority of the remaining solitary animals observed during helicopter surveys were also untreated males.

The number of treated males in a group was positively correlated to group size based on helicopter surveys (i.e., larger groups had more treated M; $R^2 = 0.765$, $F_2 = 1{,}197.785$, $P < 0.001$), although the number of treated females was not ($R^2 = 0.000$, $F_2 = 0.348$, $P = 0.706$). Of groups containing multiple treated males (≥2 treated males; $n = 106$ groups), 70.0% were mixed-sex groups ($n = 71$) and 33.0% ($n = 35$) were groups of undetermined sex composition. As an example, 1 mixed-sex group of 34 horses observed in 2013 comprised 16 treated males, 4 treated females, 13 untreated (i.e., sex unknown) individuals, and 1 foal.

Overall, each horse group (>1 horse) averaged 1.5 ± 2.7 foals/group ($n = 396$ groups) for 2008–2011 and 0.50 ± 0.81 foals/group ($n = 244$ groups) for 2012–2013 based on helicopter surveys. For groups with no fertility control treated horses, the average number of foals/group was 1.2 ± 2.3 ($n = 402$ groups). Not surprisingly, the number of foals in a group was positively correlated to group size; larger groups had more foals ($R^2 = 0.702$, $F_1 = 1{,}731.924$, $P < 0.001$). For groups with ≥1 treated males, the average number of foals/group decreased as the number of treated males within the group increased (1.05, 0.68, and 0.65 foals/group for 1, 2, or 3 treated males, respectively). A similar pattern was observed for groups with ≥1 treated females (0.67 and 0.56 foals/group for 1 or 2 treated females, respectively). However, the best predictor for the number of foals within a group was the interaction between group size and both treatments (group size × no. treated females × no. treated males; $R^2 = 0.769$, $F_3 = 816.733$, $P < 0.001$). Larger groups had more foals (ß = 0.921, $t_3 = 49.469$, $P < 0.001$), but the number of foals decreased correspondingly with increasing numbers of treated females (ß = −0.071, $t_3 = -3.685$, $P < 0.001$) and treated males (ß = −0.238, $t_3 = -11.960$, $P < 0.001$) within a group.

The foaling season on the Refuge ranged from February to September, as estimated by ages of foals captured in the fall. The peak of foaling season was between April and June (83.2% of foals born), with on average 90.8% of foals on Sheldon Refuge born by the end of June each year. In comparing peak foaling rates across the larger landscape based from fixed-wing surveys in June 2010, 2011, and 2014, values within adjacent HMAs averaged annually between 7.6 foals:100 adults and 21.0 foals:100 adults compared to the Refuge's average of 7.4 foals:100 adults; the highest observed June foaling rate was 32.2 foals:100 adults documented in the Carter Reservoir HMA in 2014 (Table 3). Observed foaling rates based on helicopter surveys between 2008 and 2014 for the Refuge population ranged from 6.0 foals:100 adults to 18.0 foals:100 adults (Table 4). Actual foaling rates for the Refuge population derived from captured individuals ranged annually from 3.4 foals:100 adults to 21.8 foals:100 adults and were comparable to annual observed estimates from July helicopter surveys (Table 4). Estimates of annual foal recruitment (post-Jul) averaged 100.1% (range 97.4–103.0%); values >100% represent the small number of foals born after June.

The application of combined fertility control treatments resulted in a decline in the population-level actual foaling rate from >20.0 foals:100 adults to <4.0 foals:100 adults within 4 years (Table 4). In our population, a greater proportion of the males received treatment compared to the number of treated females. We were able to infer that treating approximately 30% of the female population had the potential to result in substantial declines in the expected foaling rate (>20 foals:100 adults with no treatment vs. $\bar{x} = 12.0$ foals:100 adults with only

Table 3. Comparative peak foaling rates of feral horses (foals:100 adult horses) within Sheldon National Wildlife Refuge, and adjacent Bureau of Land Management Herd Management Areas (HMA) and 1 Herd Area (HA) as estimated from fixed-wing aerial survey efforts in June, 2010, 2011, and 2014, Oregon and Nevada, USA.

[a] Includes the combined effects of both treatment groups.

females treated, $\bar{x} = 28\%$ treated). In addition, treating approximately 23–47% of the male population also likely contributed to substantial declines (30–72%) in untreated female fecundity after 2007–2008 (Table 4).

DISCUSSION

The fertility control treatments we applied did not affect the survival of horses post-release. In addition, fertility control efforts were effective in reducing the population-level annual foaling rate within a short period of time (from >20% to <4% within 4 years). Annual foaling rates across the larger area peaked in June but were variable between years and across the larger landscape. Our estimates of annual foal survival in the Refuge population were high (>97%) and although we were unable to account for potential overwinter mortality during a foal's first year, we suspect it was a small influence on the Refuge, particularly given the high recapture rates over the course of this study. This indicates that free-roaming horse composition counts from aerial surveys conducted in July and later can be used to reasonably approximate annual foal recruitment in populations where annual recruitment is generally high. Although not directly tested for, we did not detect any noticeable shifts in the timing of the foaling season in response to fertility control treatments as postulated by others (Garrott and Siniff 1992, Asa 1999).

Within the relatively open habitats of the Refuge, our population estimates generated from the fixed-wing double-count technique tended to underestimate population size, although the method provided the ability to calculate confidence intervals and account for animals not seen, and the derived population size generally fell within those ranges. In contrast, uncorrected direct counts via helicopter generally tended to overestimate population size, particularly as the population began to decline as a result of increasing management activities between 2011 and 2014, and did not provide the ability to estimate confidence intervals. Helicopters were used to conduct direct count surveys and to capture the horses, and as a result individuals became increasingly familiar with and reactive to the presence of the helicopter over time; we did not observe the same degree of reactivity to the fixed-wing platform used during double-count surveys. We suspect the overestimation from the direct counts were the result of inadvertently double-counting a proportion of increasingly reactive individuals that were moving between areas and between days in response to the presence of the survey helicopter.

Limiting fertility through the use of immunocontraceptives and other techniques is becoming a more commonly considered tool for controlling free-roaming horse abundance; although the physiological changes that may accompany some of these tools have the potential to influence individual behavioral changes and alter family group structure and population dynamics (Nuñez et al 2010, Ransom et al. 2014*b*). Fertility control treated males in our study showed no difference in measurements of normal testicular endocrine function compared to untreated individuals (Scully et al. 2015), suggesting there should be no change in male breeding behaviors or social status (Asa 1999). We documented that all treated individuals appeared to maintain group associations and there were no groups consisting only of treated males or only treated females. We documented mixed-sex groups consisting of multiple treated males in all years. The social structure of free-roaming horse groups generally consists of a harem stallion, occasionally a satellite stallion, and females and offspring (Roelle et al. 2010). The duration of multiple-male bands has been thought to be short-lived, from several hours to a year (Berger 1986, Roelle et al. 2010), although Bowling and Touchberry (2001) reported that 39% of their harem bands contained multiple males; differences between populations relative to multiple male bands may be associated more with sex ratio and population density (Kirkpatrick and Turner 1986). Further, male offspring may remain with their maternal band for up to 4 years (Berger 1986) and this also could account for some of our observations. Regardless, the complexity of social behaviors among free-roaming horses is not entirely centered on reproductive receptivity, and fertility control treatments that suppress the reproductive system and reproductive behaviors should contribute to minimal changes to social behavior (Ransom et al. 2014*a*).

Cost is another factor for consideration, and there are 2 categories associated with fertility control in free-roaming horses: cost of the treatments themselves and costs associated with treatment application. The 2 commonly used temporary agents are formulations of porcine zona pellucida (PZP; ZonaStat-H and PZP-22; Science and Conservation Center, Billings, MT, USA) and are approximately $35.00/dose and $325.00/dose, respectively (A. B. Shepherd, Bureau of Land Management, personal communication). In comparison, the permanent techniques we used ranged from approximately $125/horse to $150/horse (i.e., vasectomy and ovariectomy, respectively). However, both temporary agents require repeated dosing approximately every 12 months to maintain reproductive control. Thus, assuming the average free-roaming horse lives to be at least 20 years old, estimated costs of re-dosing would range from $590/horse to $5,500/horse over the individual's lifetime. In addition are the costs associated with application; of the currently available techniques, all require the

animals to be captured and handled. Even in the case of temporary agents being used by the Bureau of Land Management, the horses are typically captured, transported to holding facilities (both temporary and permanent), and then held in captivity for days to months while individuals slated for treatment and release are selected (A. B. Shepherd, personal communication). Thus, although capture, transport, and holding would be a one-time expense in the case of permanent treatments, the repeated dosing required for temporary treatments also would require repeated handling and substantially increase the cost per horse (i.e., >$1,000/horse/capture). Further, each additional capture event also increases the risk of injury or death to individuals. In very rare cases, some free-roaming horse herds have been sufficiently habituated to humans and are able to be approached (<36 m) and remotely darted with a temporary contraceptive agent (A. B. Shepherd, personal communication). In those specific circumstances, long-term reproductive control could potentially be maintained without repeated capture events; however, although this approach is gaining popularity with some members of the public, this scenario is not realistic for the majority of free-roaming horse herds occupying public rangelands in the western United States.

As discussed, social structure may be an important consideration in the efficacy of fertility control in free-roaming horses. For example, previous efforts to control fertility in male free-roaming horses reported that permanent sterilization limited to socially dominant males may be effective in reducing foaling rates in individual, stable groups. However, it was postulated that it might not effectively suppress overall population growth unless a large proportion of the males were treated (Garrott and Siniff 1992, Eagle et al. 1993, Ransom et al. 2014*b*). Hence, our efforts did not target only socially dominant individuals but sought to saturate the study area with permanently treated animals, both males and females, and as such, we saw an almost immediate reduction in foaling rates at the group- and population-levels. Our results indicate that a combination of effective measures are currently available that can reduce annual foaling rates without the majority of individuals maintained as non-reproductive, and that these measures can be used to successfully control population growth in large populations of free-roaming horses.

MANAGEMENT IMPLICATIONS

One primary advantage of permanent fertility control is that treated animals do not require repeated exposure to potentially risky capture and handling to maintain reproductive control. Our findings demonstrate that maintaining a proportion of a population as permanently non-reproducing has the potential to safely reduce annual foaling rates within a short period of time, and provide managers the ability to start to attain and then maintain free-roaming horse herds at desired management levels. Regardless of the technique selected, foregoing any measures to control annual foaling rates will require the continuation of frequent, high-profile, controversial capture operations, with the consequent, unsustainable management of free-roaming horses and associated declines in rangeland ecological health, unless even more drastic measures are undertaken.

ACKNOWLEDGMENTS

The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service. Any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government. The Bureau of Land Management provided support for a portion of the aerial surveys. Cattoor's Livestock Roundup provided helicopter gather and transportation services. JL Aviation, Owyhee Air Research, El Aero Services, and Sunstone Aviation provided aerial survey services. Aerial surveys were assisted by J. D. Axtell, B. H. Day, J. Fox, P. C. Griffin, R. Knox, S. P. Ludwig, K. López, C. O'Connor, J. Parsons, J. W. Price, S. Soletti, S. Surian, and A. Whitman. L. G. Pielstick provided veterinary services and J. M. Weikel provided program review and animal welfare oversight. We thank B. H. Day, P. F. Steblein, D. F. Miller, S. P. Ludwig, R. L. West, G. Albertson, A. P. Collins, G. Eckel, J. Elizararras, K. López, J. NMN. Mackay, J. Megan, M. Nagel, R. Portwood, M. Solus, K. A. Trust, M. R. Webster, J. Wehrley, and numerous others for invaluable project support. Additional support was provided by Nevada Bighorns Unlimited and The Greater Hart-Sheldon Conservation Fund. A. B. Shepherd provided information on the Bureau of Land Management's Wild Horse and Burro Program. Comments by P. C. Griffin and A. B. Shepherd improved early drafts of the manuscript. We appreciate the critical insights of the editors and reviewers. This work was supported by the U.S. Fish and Wildlife Service.

Abstract

Reproductive behavior of virtually all adult male rodents is dependent on concurrent availability of gonadal steroids. The ejaculatory reflex is incompatible with long-term absence of testicular steroids and typically disappears within 3 weeks after castration. Male Siberian hamsters are an exception to this rule; mating culminating in the ejaculatory reflex occurs as many as 6 months after castration (persistent copulation). The emergence of persistent copulation many weeks after gonadectomy is here shown not to require repeated post-castration sexual experience. Preoperative sexual experience, on the other hand, significantly increases the percent of males that copulate after gonadectomy, but is not required for the emergence of this trait in 25% of males. Castration prior to puberty prevents persistent copulation in all individuals in adulthood. Persistent copulators, unlike males that cease mating activity after castration, prefer the odors of estrous over non-estrous females when tested 4 months after castration and 7 weeks after the last mating test. Neural circuits of persistent copulators retain the ability to mediate male sex behavior and preferences for female odors in the complete absence of gonadal steroids; they are influenced by preoperative sexual experience and organizational effects of gonadal hormones at the time of puberty.

Introduction

Copulatory behavior of most adult male mammals is dependent on concurrent availability of gonadal hormones. In the most well studied animal models, castration of adults leads to a rapid decline in male sexual behavior that is reversible with testosterone treatment (Young, 1961; Sachs and Meisel, 1988). Testicular hormones affect both appetitive and consummatory components of male copulation (Beach, 1956; Davidson, 1972). Beginning a few weeks after castration male rodents paired with estrous females no longer display the distinct intromission and ejaculatory behaviors characteristic of intact animals (rats, Davidson, 1966; guinea pigs, Grunt and Young, 1952; Syrian hamsters, Beach and Pauker, 1949; mice, McGill and Tucker, 1964). Only rarely do males of these species sustain ejaculatory behavior for more than a few weeks after castration (e.g., Davidson, 1966). B6D2F-1 hybrid mice, 30–80% of which retain the ejaculatory reflex 5–6 months after orchidectomy (Manning and Thompson, 1976; Clemens et al., 1988; Wee and Clemens, 1989), and Siberian hamsters, approximately one third of which maintain the complete copulation pattern for 4–6 months after castration (Park et al., 2004), are exceptions to this rule. Furthermore, 50% of Siberian hamsters that undergo testicular regression in short winter photoperiods also continue to display the ejaculation reflex despite low to undetectable blood testosterone concentrations (Park et al., 2004). The long-term persistence of copulation in inbred mice does not require the presence of adrenal hormones (Thompson et al., 1976).

Preoperative sexual experience facilitates retention of male sex behavior in mice (Manning and Thompson, 1976), cats (Rosenblatt and Aronson, 1958) and Syrian hamsters (Bunnell and Kimmel, 1965; Lisk and Heimann, 1980) castrated in

doi:10.1016/j.yhbeh.2006.09.007

adulthood as well as Syrian hamsters subjected to ablation of the vomeronasal organ (Meredith, 1986). In contrast, prior sexual experience does not promote retention of sex behavior in orchidectomized rats (Rabedeau and Whalen, 1959; Bloch and Davidson, 1968) and dogs (Hart, 1968; Beach, 1970).

In a previous study, male Siberian hamsters that continued to copulate many weeks after castration (persistent copulators) were sexually experienced at the time of orchidectomy, and were tested bi-weekly beginning 1 week after castration (Park et al., 2004). The present study, which assesses the role of pre- and postoperative sexual experiences in the retention of mating behavior after castration, parallels earlier investigations of B6D2F-1 mice (Manning and Thompson, 1976; Wee and Clemens, 1989). Because pubertal testicular hormones organize sex behavior in hamsters (reviewed in Schulz and Sisk, 2006), we also determined whether prepubertal castration was compatible with persistent copulation in adulthood.

Copulation in rodents is conceived as completely dependent on a combination of chemosensory cues and hormones (Wood, 1997; Wood and Newman, 1995). Sexually experienced male rats (Stern, 1970; Paredes et al., 1998) and Syrian hamsters (Fiber and Swann, 1996; Swann, 1997) prefer the odors of estrous females over those of non-estrous females or males. This preference disappears a few weeks after castration, and is restored by testosterone treatment (e.g., Stern, 1970 for rats; Gregory et al., 1975 for Syrian hamsters). The loss of this olfactory preference may contribute to the males' reduced mating activity after castration.

The present investigation further characterizes the post-castration persistent copulator phenotype of Siberian hamsters by extending observations to another behavior: the male's preference for estrous female odors. Males that displayed the ejaculation reflex 7 or more weeks after castration were designated persistent copulators. To test the hypothesis that persistent copulators would remain attracted to odors of estrous females, we assessed olfactory preferences of castrated male Siberian hamsters that either had stopped copulating or continued to mate for several months after castration. Testing was conducted 4 months after castration and approximately 7 weeks after the most recent mating test.

Materials and methods

Animals

Siberian hamsters (*Phodopus sungorus sungorus*) were from our local breeding colony, descended from stock originally supplied by Bruce Goldman (University of Connecticut, Storrs, CT) and later outbred to hamsters supplied by Katherine Wynne-Edwards (Queen's University, Kingston, ON). All procedures were approved by the Animal Care and Use Committee of the University of California at Berkeley.

To facilitate behavioral testing during the daytime, hamsters entrained to an LD 14:10 photocycle (14 h light/day with onset of darkness at 1300 h PST) were mated. Males weaned at 18 days of age were housed individually in polypropylene cages (25×14×12 cm). Food (Purina rodent chow 5015) and water were provided *ad libitum*, and the ambient temperature was 22±2°C.

Female hamsters used in behavioral testing were ovariectomized at approximately 60 days of age and were treated with 4 mm Silastic capsules implanted subcutaneously (Dow Corning, Midland, MI, USA; ID 1.98 mm, OD 3.18 mm). Capsules filled with crystalline estradiol benzoate (EB; Sigma Chemical, St. Louis, MO, USA) were soaked in sterile saline solution for 24 h prior to implantation. To induce behavioral estrus each female was injected with progesterone (0.6 mg/0.1 ml peanut oil, sc; Sigma) 6 h prior to testing. Stimulus females were maintained in the same 14 L photoperiod as the males.

Mating test

Testing, conducted under dim red light between 1400 and 1700 h in the male's home cage, began with the introduction of a hormonally-treated stimulus female. If the female failed to display receptive behavior in response to male approaches within 10 min, she was replaced with another female. Otherwise the male's behavior was recorded for 30 min, or until 2 ejaculation reflexes were observed, whichever occurred first. Observation was terminated after 20 min if the male failed to mount the second female.

Data were collected as described by Park et al. (2004). The information recorded included: the number of mounts not accompanied by an intromission that preceded an ejaculation, the number of intromissions that preceded each ejaculation, latencies to the first mount, first intromission, and first ejaculation, and the duration of the post-ejaculatory interval, which is the time between an ejaculation and the next intromission. Males that failed to mount, intromit, or ejaculate were assigned the maximum copulation latency of 1800 s. Males were considered persistent copulators when mating culminating in the ejaculation reflex was recorded on one or more post-castration tests at least 7 weeks after gonadectomy.

Olfactory preference testing

Feces were collected from hormonally primed, sexually receptive females and from untreated ovariectomized females. Females were housed without bedding for 4–6 h during fecal collection. Feces were removed just before the onset of the dark phase (1300 h), 4–6 h after hormonally-treated females had been injected with progesterone. Five feces of each type, placed into separate Petri dishes (5 cm in diameter), were inserted to opposite ends of the male's home cage, and his behavior recorded for 10 min. The positions of the two dishes (A and B) were randomized. The amount of time the males spent investigating each dish in which the male was in direct physical contact with the feces was recorded. Groups were considered to prefer odors from dish A if the mean of investigatory time spent in contact with feces from dish A was significantly higher than that spent investigating feces from dish B.

Morphological parameters

Hamsters were anesthetized with isoflurane vapors, and the testes were weighed (±0.1 mg) within 10 min of extraction. Body weights were obtained at the time of surgery (±0.1 g).

Statistical analysis

The Statview program (Statview 5; SAS Institute, Cary, NC, USA) was used for all analyses. Differences in copulatory behavior between groups at certain weeks were assessed with the Chi square measure. Repeated measures ANOVAs were used to analyze changes in the number of mounts and intromissions, and mount, intromission and ejaculation latencies over time. When an effect of time was present, paired *t*-tests were used to analyze differences between two time points within groups. Post-hoc comparisons were conducted using the Fisher Protected Least Significant Difference test where appropriate. Observed differences were considered significant if $p<0.05$.

Experiment 1: Effects of post-castration experience on persistent copulation

After successfully completing three of four mating tests ending in ejaculation, 20 hamsters were castrated as described in Park et al. (2003); 9 of these males were tested for copulatory behavior every other week for 7 weeks, beginning 1 week after castration. The remaining 11 animals were first re-tested 7 weeks after castration.

Experiment 2: Effects of preoperative sexual experience and puberty on copulation in adulthood

Twelve sexually naive male hamsters were castrated at 18 days of age, approximately 2–3 weeks before puberty (Hoffmann, 1978). Twenty-four hamsters were castrated postpubertally at ~70 days of age. Twelve of the latter animals had been given sexual experience culminating in ejaculation once a week for 3 weeks prior to castration, and 12 were sexually naive at the time of castration. All castrated males were tested with sexually receptive females once a week for 3 weeks, beginning at approximately 4 months of age. The interval between castration and the first mating test was approximately 13, 7, and 7 weeks for the prepubertal, sexually naive and sexually experienced males, respectively. Seven weeks after completion of the mating behavior tests and 4 months after the hamsters were orchidectomized, male attraction to female odors was assessed.

Results

Experiment 1: Effects of post-castration experience on persistent copulation

Males first re-tested with estrous females 7 weeks after castration were at least as likely to be persistent copulators as were males tested with females every 2 weeks post-castration (91% vs. 67%, respectively; $p>0.05$; Fig. 1A). Repeated post-operative sexual experience at bi-weekly intervals is not a prerequisite for the emergence of persistent copulation.

There were no significant differences between the two groups of persistent copulators with respect to mount, intromission, or ejaculation latencies or the duration of the post-ejaculatory interval during the postoperative test 7 weeks after castration ($p>0.05$), although a trend toward shorter latencies was apparent in the males given their first postoperative test 7 weeks after castration (Figs. 1B–E; only males that ejaculated on post-operative test 7 were included in this analysis).

During preoperative testing, mount latency (ML), intromission latency (IL), ejaculation latency (EL), and the post-ejaculatory interval (PEI) were progressively shorter on successive mating tests for both groups of hamsters (Figs. 1B–E). The difference was significant for 3 of the 4 measures for each group ($p<0.05$ for week −4 versus week −1 values; Figs. 1B–E).

The EL and the PEI were significantly longer during the first two postoperative tests of males tested bi-weekly beginning 1 week after castration ($p<0.05$ in each case), but by the fourth test 7 weeks after castration, both measures returned to values that did not differ significantly from preoperative baseline values 1 week prior to castration. ML, IL, and EL values of males first

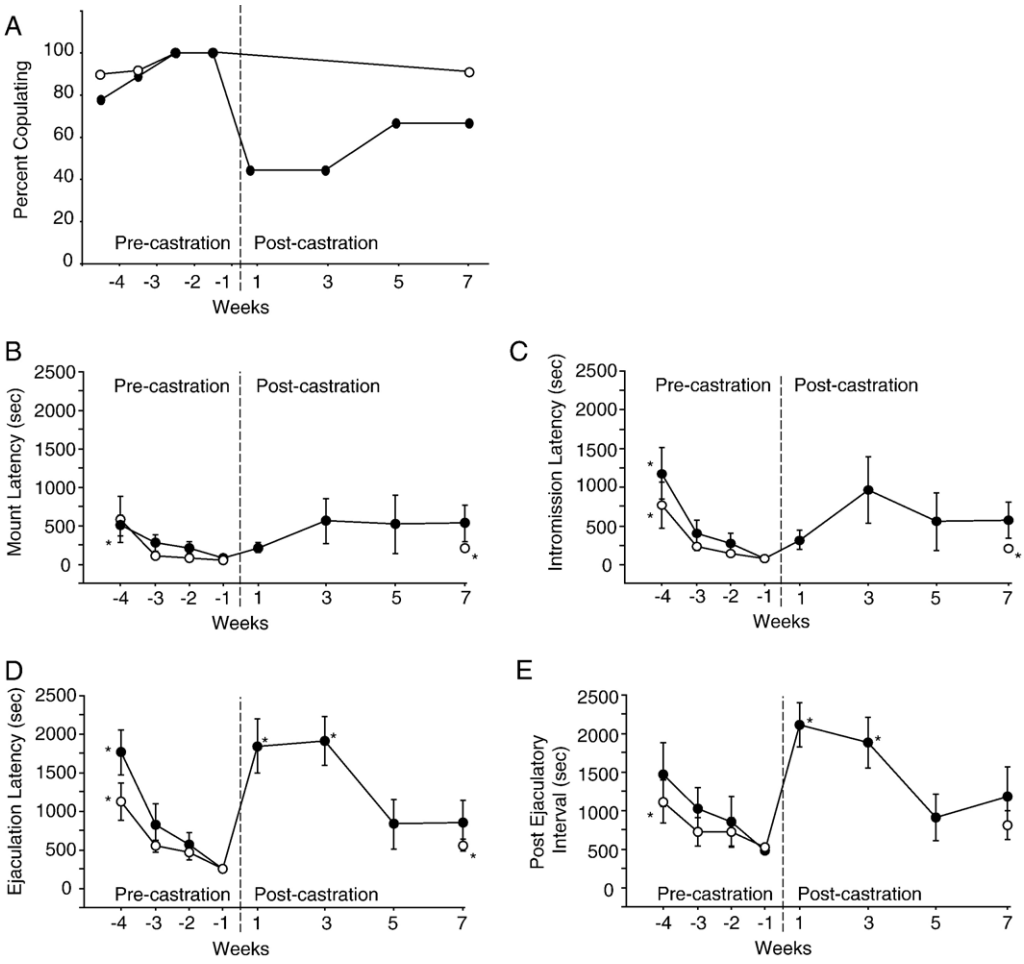

Fig. 1. (A) Percent of males copulating each week to a criterion of behavioral ejaculation. One group of males was tested bi-weekly beginning 1 week after castration (filled circles; $N=9$) and the other was first tested 7 weeks after castration (open circles; $N=11$). Mean±SEM (B) mount, (C) intromission, and (D) ejaculation latencies and (E) post ejaculatory interval of persistent copulators (those that that ejaculated 7 weeks after castration) tested bi-weekly beginning 1 week after castration (filled circles; $N=6$) and first tested 7 weeks after castration (open circles; $N=10$). *Significantly different from respective pre-castration values at week −1 ($p<0.05$).

retested 7 weeks after castration were significantly higher than preoperative week−1 baseline values (Fig. 1B–D), whereas their PEI values were not (Fig. 1E). Although the latency measures at week 7 of the animals tested bi-weekly were also higher than their week−1 baseline values, these comparisons failed to reach significance (p values ranged from 0.08 to 0.13).

Experiment 2: Effects of preoperative sexual experience and puberty on copulation in adulthood

Copulatory behavior

As in experiment 1, a majority (58%) of the adult sexually experienced males copulated to a criterion of behavioral ejaculation 7 or more weeks post-castration, compared to 25% of sexually naive males ($p<0.05$, Fig. 2A). None of the males castrated prior to puberty mounted the females, and thus never successfully intromitted or ejaculated.

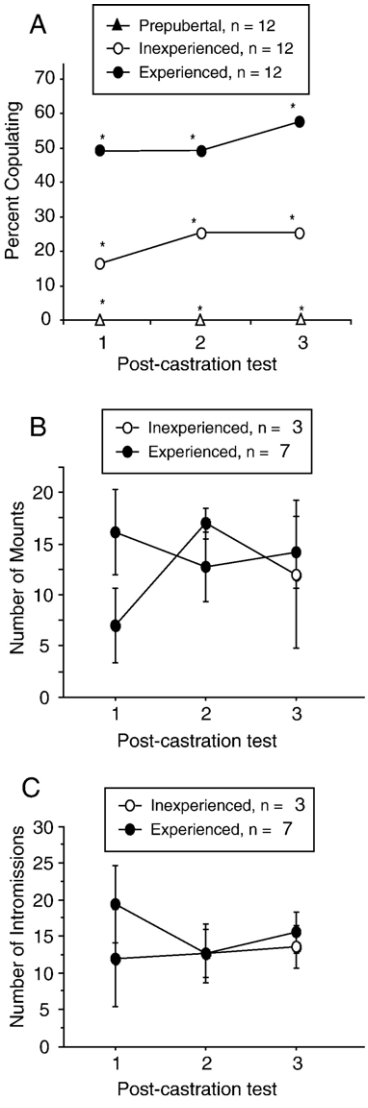

Fig. 2. (A) Percent of males copulating to a criterion of behavioral ejaculation after castration. The interval between castration and the subsequent mating test was ~13, 7, and 7 weeks for the prepubertal, adult sexually naive, and adult sexually experienced males, respectively. *The three groups were significantly different from each other ($p<0.05$). Mean±SEM number of (B) mounts and (C) intromissions by persistent copulators preceding the first behavioral ejaculation in each of the postoperative tests.

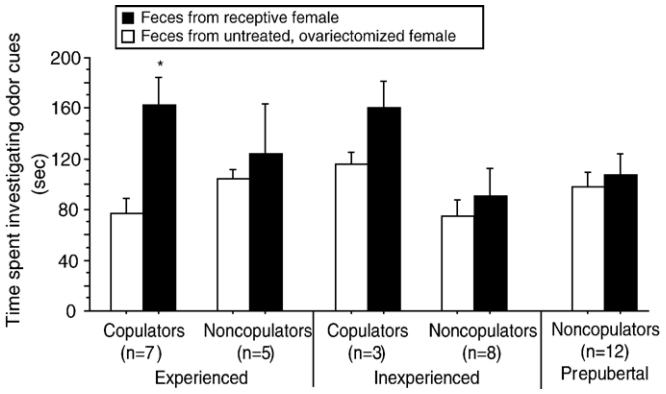

Fig. 3. Mean±SEM investigatory time directed toward feces from sexually receptive females or untreated ovariectomized females. Only sexually experienced persistent copulators ($n=7$) spent significantly more time investigating feces from estrous than non-estrous females (*$p<0.05$).

There were no differences in either the number of mounts or intromissions ($p>0.05$; Figs. 2B, C) or latencies to mount or intromission ($p>0.05$; data not shown) between the sexually experienced and sexually naive males once they displayed these behaviors.

Morphology

Body weights were significantly different between all three treatment groups at the time of castration; sexually naive males were heaviest and prepubertal males lightest ($p<0.05$, not illustrated). The experienced and inexperienced males were castrated at approximately the same age, but the prepubertal males were about 7 weeks younger at the time of gonadectomy.

Testes mass

At the time of castration sexually-experienced adult males had heavier testes than inexperienced males of the same age, 660±17 mg and 514±50 mg, respectively, as previously reported for male rats (Taylor et al., 1983). The testes removed from prepubertal hamsters were undeveloped (106±6 mg).

Olfactory preference tests

Sexually experienced persistent copulators that were castrated after puberty spent a significantly greater portion of time investigating feces from sexually receptive than non-receptive females ($p<0.05$; Fig. 3). Although inexperienced persistent copulators also spent more time investigating feces from estrous females, this comparison was not statistically significant ($p>0.05$), likely because of small sample size. None of the non-copulator groups showed a preference for either type of feces ($p>0.05$).

Discussion

Sexually experienced males successfully bridged a long gap without sexual activity and manifested the complete sex behavior repertoire when first re-tested 7 weeks after castration. The

persistence of copulatory behavior in long-term castrated Siberian hamsters was not dependent on intermittent post-operative sexual experience or priming provided by such tests. Weekly testing after castration also was not necessary for the emergence of persistent copulation in B6D2F1 mice (Wee and Clemens, 1989). Pre-operative sexual experience did, however, increase the incidence of post-castration sex behavior, perhaps in part by inducing long-term changes in penile morphology (Taylor et al., 1983); in the present study 58% of sexually-experienced hamsters, compared to 25% of sexually-naive hamsters, continued to copulate postoperatively.

The decreased incidence of gonad-independent sex behavior in naive hamsters was not unexpected. Prior sexual experience renders neural substrates less dependent on androgens (Hart, 1974). The benefits of sexual experience for retention of mating behavior after castration have been documented in cats and Syrian hamsters (Rosenblatt and Aronson, 1958; Bunnell and Kimmel, 1965; Bunnell and Flesher, 1965; Lisk and Heimann, 1980). Remarkably, 25% of sexually naive males copulated to a criterion of behavioral ejaculation when first tested 7 weeks after castration. Concurrent availability of gonadal hormones is required by most sexually naive adult Siberian hamsters for activation of copulatory behavior in adulthood, but a minority of naive males is not so constrained. The neural substrate of the latter hamsters was able to support sex behavior many weeks after the withdrawal of gonadal steroids. The extent to which activation of neural mating circuits is similar in castrated persistent copulators and gonadally-intact males, is unknown.

Persistent copulation was absent in males castrated prepubertally and tested in adulthood. None of these males even attempted to mount females. The combined absence of precastration sexual experience and pubertal hormone secretion was incompatible with persistent copulation in adulthood; the absence of mounting behavior reflects a lack of sexual arousal and motivation (Sachs and Meisel, 1988). The significantly lighter penises of prepubertal castrates (Park et al., 2003) may also prevent normal copulation. The experimental design we employed controlled for age at the time of testing, but the interval between castration and the first postoperative mating test was 13 weeks for the prepubertal and 7 weeks for the postpubertal males and may have contributed to the mating deficit in the former animals. The extended interval after castration is unlikely to explain the complete absence of copulatory behaviors in this group, as 40% of adult Siberian hamsters continue to display the complete repertoire of mating behaviors 13 weeks after castration (Park et al., 2004). Differences in methodologies between the two studies, however, prevent definitive conclusions. Pubertal testicular hormone secretion is required for normal adult mating behavior of Syrian hamster (reviewed in Schulz and Sisk, 2006) and here is implicated in the emergence of gonad-independent persistent copulation of Siberian hamsters.

Emancipation from strict hormonal control of mating activity in male mammals was formerly thought to be restricted to carnivores and primates. Some dogs continue to copulate for years after gonadectomy (Hart, 1968) and some untreated men reportedly engage in sexual intercourse a decade after bilateral orchidectomy (Heim and Hursch, 1979; Weinberger et al., 2005). Increased cerebral cortical influences were the proposed mediators of long-term maintenance of mating behavior in gonadectomized males (Ford and Beach, 1951) but subsequent analyses failed to document a correspondence between degree of brain development and corticalization on the one hand, and post-castration retention of male sex behavior, on the other (Aronson, 1959; Hart, 1974; Manning and Thompson, 1976; McGill and Manning, 1976; Clemens et al., 1988; Park et al., 2004, present study).

Persistence of olfactory preferences in castrated males has not to our knowledge been reported previously for any rodent (see Paredes et al., 1998 for a review of the older literature). We demonstrated that sexually experienced persistent copulators prefer the odors of estrous females, but such preferences were absent in experienced and inexperienced non-persistent copulators, as well as males castrated prior to puberty. Male rat preferences for odors of estrous females disappear 3 weeks after castration and are restored by testosterone treatment (Stern, 1970). The robust preference of sexually-experienced persistent copulators for the odors of sexually receptive females is therefore remarkable, considering that tests were conducted 7 weeks after the last mating test and 4 months after castration. Responsiveness to sexually salient odors may be causally related to post-castration emergence of persistence copulation.

Our results suggest but do not definitively establish that the amount of prior sexual experience may influence post-castration preference for estrous odors. It is unknown whether gonadal steroids are required for initial establishment of the male's preference for estrous odors or if this preference subsequently becomes steroid-independent. Alternatively, a subset of sexually naive castrated male hamsters may have strong preferences for the odors of estrous females prior to the first mating test; perhaps only those males subsequently develop persistent copulation.

During odor tests, fos-like immunoreactivity is detected in more brain areas throughout the vomeronasal pathway and the nucleus accumbens of sexually experienced than sexually naive male rats. Sexual experience may be necessary for full activation of this pathway (Hosokawa and Chiba, 2005). It remains to be specified whether the olfactory mating circuit of persistent copulators responds differently than that of non-persistent copulators to salient female odors (cf. Kollack-Walker and Newman, 1997; Wood and Newman, 1995), although we consider this likely. Retention of mating and olfactory behaviors in persistent copulators may be dependent on neurosteroids (Frye, 2001), or constitutively activated steroid receptors (Blaustein, 2004), but is unlikely to depend on adrenal estrogens or androgens, as evidenced by the persistence of male sexual behavior in castrated hybrid B6D2F1 hybrid mice after adrenalectomy (Thompson et al., 1976).

It is also unknown whether all gonadally-mediated traits are retained to a greater extent in persistent copulators than in males that cease mating activity after castration. Persistent copulators may fail to manifest the increased aggressive behavior that follows castration in Siberian hamsters (Jasnow et al., 2000). Castration does not affect all androgen-dependent traits or all

genotypes equally; e.g., all Long–Evans rats failed to copulate several weeks after castration but ultrasonic vocalizations decreased markedly in half the animals and increased above preoperative values in the remaining rats (Matochik and Barfield, 1994). Similarly diverse responses were observed in meadow voles subject to castration; heavier voles decreased and lighter voles increased their body mass postoperatively (Dark et al., 1987).

Future studies of persistent copulators stand to increase our understanding of the mechanisms by which environmental factors, sensory systems, and neurotransmitters sustain male sex behavior in the absence of gonadal steroids.

Critically Appraised Topic

Can ovariectomy be justified on grounds of behaviour?

J. R. Crabtree

Equine Reproductive Services (UK) Limited, Old Malton, UK.
Corresponding author email: james.r.crabtree@gmail.com

Clinical scenario

In practice, clinicians are commonly presented with mares reportedly behaving 'badly' either persistently or at regular or irregular intervals. This behaviour is often presumed by the owners or riders to be due to their mares being in oestrous or their reproductive hormone balance. Undesirable behaviour is varied and includes an unwillingness to respond to rider instruction or signals, bucking, rearing, overt reproductive behaviours, aggression and stallion-like behaviour (Hedberg *et al*. 2007a; Kamm and Hendrickson 2007; Crabtree 2011). It is assumed that when considering these behavioural problems, the behaviour in question has been confirmed by the clinician to be temporarily associated with the oestrus cycle or with ovarian pain and not musculoskeletal, soft tissue, gastric or dental pain. The question has been refined to exclude those behavioural issues experienced due to the presence of granulosa cell tumour (GCT; Crabtree 2011). These criteria define the population of mares for the question, 'can ovariectomy on grounds of behaviour be justified?' The question is not an ethical one, rather whether or not behaviour can be improved with surgery.

Search strategy

Pubmed/Medline (http://www.ncbi.nlm.nih.gov/pubmed), the University of Liverpool electronic library search (http://www.liv.ac.uk.ezproxy.liv.ac.uk/library) and IVIS (http://www.ivis.org): ovariectomy AND mare AND behaviour. Hand searching of references in all articles identified and those within the author's knowledge was conducted. In addition a request for references and opinions was made via a private worldwide equine reproduction e-mail network.

Quantity of evidence

Sixteen, 41 and 18 papers were retrieved respectively; relevance screening was conducted based on abstracts identifying 3 papers applicable to the question in the last 30 years. Of the 3 papers there was one randomised controlled trial (Hedberg *et al*. 2007b) and 2 retrospective studies (Hooper *et al*. 1993; Kamm and Hendrickson 2007).

Quality of evidence

The study by Hooper and co-workers (1993) looked retrospectively at 23 cases of bilateral ovariectomy between 1984 and 1990 by client survey. Of the 23 cases, 16 were for the purpose of behaviour modification and 7 were for other reasons not including ovarian pathology. Kamm and Hendrickson (2007) reported the results of a retrospective study of 35 cases between 1996 and 2005 by client survey. The reported data included both bilateral and unilateral ovariectomy with the latter being due to ovarian pathology. Twenty-three mares had bilateral ovariectomy for behavioural problems. These retrospective observational studies, based on client opinion, represent relatively weak evidence; in addition they are inherently biased. The study by Hedberg and co-workers (2007b) primarily looked at the effect of ACTH (tetracosactide) on steroid hormone levels in 5 intact vs. 5 ovariectomised mares. The mares acted as their own controls and the study was conducted in successive years (2003–2004). Of the parameters measured, oestrous behaviour was assessed by daily teasing with a stallion. Teasing behaviour was assessed using a standardised protocol and scored. This prospective case–control design has greater evidentiary value than the retrospective study despite the low numbers. Teasing scores however, were not subject to statistical analysis and remained observational. This paper formed part of a greater work which looked at the adrenal response to ACTH between normal and 'problem' mares (Hedberg *et al*. 2007a).

Clinical implications

Hedberg and co-workers (2007b) demonstrated that ovariectomy resulted in continued displays of sexual receptiveness in all mares with a loss of normal cyclic activity. Ovariectomised mares showed more days of oestrus compared with when they were intact; 44 days of oestrus for all intact mares compared with 152 days for all ovariectomised mares during the study period. One ovariectomised mare showed 78 consecutive days of oestrus. This finding is supported by the author's experience and earlier published observations that ovaries are not essential for oestrus behaviour in the mare (Asa *et al*. 1980; Wesson and Ginther 1981).

Hooper and co-workers (1993) reported that 35% of mares demonstrated continued oestrus behaviour. In 9% of cases this was judged to be 'objectionable' by the owners. Of 12 performance mares, 10 were judged to be competing at greater than preoperative levels. In the report by Kamm and Hendrickson (2007) 22% of owners reported that they were either impartial or dissatisfied mainly due to a failure of behavioural change following surgery. More generalised behavioural problems were more likely to be corrected with an ovariectomy than more specific behavioural issues. Aggressive behaviour and a generalised disagreeable demeanour were most commonly corrected (86 and 81% respectively), followed by excitability (75%), kicking and biting (73%), and problems during training that related to oestrus-like behaviour (72%). Problems with other horses and frequent urination were less likely to be improved after surgery (64%). None of the studies addressed the concept of ovarian pain as a cause of subtle behavioural issues encountered in ridden competition horses.

Clinical message

The current data would suggest that if the undesirable behaviour which prompts presentation is normal sexual

© 2015 EVJ Ltd

(oestrus) behaviour then the likelihood is that ovariectomy will not correct the problem. In fact ovariectomy may make the situation worse as oestrus behaviour may become irregular and/or persistent post surgery. If the behaviour is aggressive in character then ovariectomy is more likely to be a successful therapy but the evidence for this is weak. If ovarian pain is considered as a cause of abnormal behaviour then inducing ovarian inactivity via the use of a GnRH vaccine may be a viable option that does not require surgery, however, mares vaccinated against GnRH will also demonstrate oestrus behaviour (Dalin *et al*. 2002). Future studies with accurate definition of the cause, or characteristics of, the behaviour with matched controls may enable a more definitive answer to the question.

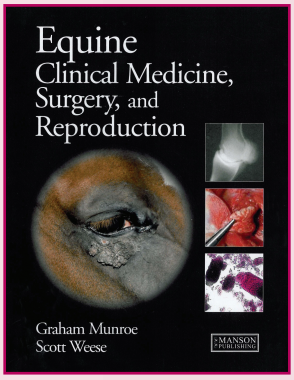
EQUINE VETERINARY JOURNAL BOOKSHOP

Equine Clinical Medicine, Surgery, and Reproduction

Graham Munroe and Scott Weese



Publisher: Manson Publishing • Hardback, 1056 pages • January 2011

Over 30 internationally respected editors and authors have combined to produce this major new textbook and reference source in a single volume, covering all aspects of equine medicine, surgery and reproduction. The text is supported by a wealth of over 1300 illustrations of the highest quality - colour photographs, radiographic and ultrasound images, and diagrams.

The book is system-based and each individual system is introduced with precise information on the relevant basic anatomy and physiology, standard clinical examination techniques and useful differential diagnostic aids. This is followed by diseases and disorders that are pertinent to that system, grouped together either anatomically or based on presenting clinical signs. Each condition is described using consistent headings – definition/overview, aetiology and pathophysiology, clinical presentation, diagnosis, differential diagnoses, management/treatment, and prognosis. Additional chapters deal with the foal, with wounds and behavioural problems.

The focus throughout is on providing clinically relevant information required for practical case management, plus sufficient background on causes and disease processes to enable readers to understand the conditions and the rationale for diagnostic and treatment options.

Equine Clinical Medicine, Surgery, and Reproduction will be of lasting value as a teaching and training resource for equine specialists, a ready reference for non-specialist practitioners, and a textbook for students in veterinary medicine and related equine courses.

THE ECOLOGY OF STRESS

The ecology of stress: effects of the social environment

Scott Creel*[,1], Ben Dantzer[2], Wolfgang Goymann[3] and Dustin R. Rubenstein[4]

[1]*Conservation Biology & Ecology Program, Department of Ecology, Montana State University, Bozeman, Montana, 59717 USA;* [2]*Department of Zoology, Michigan State University, East Lansing, Michigan, 48824, USA;* [3]*Abteilung Verhaltensneurobiologie, Max-Planck-Institut für Ornithologie, Eberhard-Gwinner-Straße, Haus 6a, D-82319, Seewiesen, Germany; and* [4]*Department of Ecology, Evolution and Environmental Biology, Columbia University, 10th Floor Schermerhorn Extension, MC 5557, 1200 Amsterdam Avenue, New York, New York, 10027 USA*

Summary

1. Many aspects of the social environment affect hypothalamic-pituitary-adrenal (HPA) axis function and increase circulating glucocorticoid concentrations. In this review, we examine the relationships between the social environment and the function of the HPA axis in vertebrates.

2. First, we explore the effects of the social environment on glucocorticoid secretion in territorial (primarily non-social) species, with an emphasis on the effects of variation in population density, as modified by environmental factors such as predation risk and food availability. In general, high population density or frequent territorial intrusions are associated with increased glucocorticoid secretion in a wide range of taxa, including mammals, birds, fish and reptiles, although there is considerable variability across species.

3. Second, we consider the effects of social interactions and dominance rank on glucocorticoid secretion in social species, mostly in birds and mammals. We review studies that have detected an association between social status and glucocorticoid levels – sometimes with higher glucocorticoid levels in low-ranking individuals, and sometimes with higher glucocorticoid levels in dominant individuals. The relationship between dominance and glucocorticoid levels varies among species, populations and years, in a manner that depends on the stability of the social hierarchy, environmental conditions, the type of breeding system, and the manner in which high rank is obtained and maintained.

4. Finally, we discuss the concept of allostasis and consider interactions between social effects and other environmental factors, noting that there is relatively little research on these interactions to date. For both non-social and social species, we identify priorities of future research. These priorities include more complete descriptions of HPA function that move beyond measurements of basal glucocorticoid concentrations (which will generally require field experiments), to studies that examine organizational effects of social stressors, that directly test the relationship between HPA function and fitness, and that examine how glucocorticoid responses affect population dynamics.

5. Although several lines of evidence suggest that glucocorticoid responses can affect the fitness of individuals and therefore can alter the dynamics of populations, the effect of glucocorticoid responses on population dynamics remains essentially unstudied.

Key-words: allostasis, dominance, glucocorticoid, hypothalamic-pituitary-adrenal axis, sociality, social behaviour, stress, territoriality

Introduction

Animals are faced with a constant flood of information from their external environment. Although much of this information can be ignored, some of it can be used in an adaptive fashion. In vertebrates, one of the primary mechanisms by which external environmental information elicits such an adaptive response is through initiating a physiological cascade of internal changes mediated in part through the hypothalamic-pituitary-adrenal (HPA) axis.

The HPA axis is the neuroendocrine pathway by which stress hormones (glucocorticoids) are released from the adrenal cortex. The structure and function of the HPA axis are reviewed elsewhere (e.g. Sapolsky, Romero & Munck 2000; Sapolsky 2002). The HPA axis integrates environmental information and the downstream release of glucocorticoids can potentiate an adaptive behavioural response (Monclús *et al.* 2005; Schulkin, Morgan & Rosen 2005) or alteration in life-history strategy (Wingfield *et al.* 1998; Boonstra 2005).

The social environment is one of the primary sources of information that can induce a physiological stress response. In both social and non-social animals, the frequency and type of interaction with conspecifics as well as status in social species can affect HPA axis activity. In this review, we examine the relationships between the social environment and the function of the HPA axis in vertebrates. First, we explore the effects of the social environment on glucocorticoid secretion in territorial species, with an emphasis on the effects of variation in population density, as modified by environmental factors such as predation risk and food availability. Second, we consider the effects of social interactions and dominance rank on glucocorticoid secretion in social species. Many studies have detected an association between social status and glucocorticoid levels – sometimes with higher glucocorticoids in low-ranking individuals, and sometimes with higher glucocorticoids in dominant individuals. Many studies also consider the particular traits associated with dominance or subordination that might be causally related to variation in glucocorticoid secretion. Other studies suggest that the general social environment (e.g. the stability or instability of social relationships and the type of dominance hierarchy) can affect the association between glucocorticoids and rank. Finally, we discuss the concept of allostasis and consider interactions between social effects and other environmental factors, noting that there is relatively little research on these interactions to date. Thus, this review reveals relationships between glucocorticoid secretion, environmental variables such as predation risk, population variables such as density or the rate of territorial intrusion and social variables such as dominance rank, and behavioural variables such as the rate of aggression. Clearly the HPA response is a physiological mechanism that might mediate a wide range of fitness effects. The review also reveals considerable variability among species in the response of glucocorticoid levels to these factors and suggests new hypotheses that might explain this variation.

Effect of the social environment on the stress axis in territorial vertebrates

NON-SOCIAL SPECIES: TERRITORIALITY

The patchy distribution of limited but defendable resources such as food, mates or preferable habitats can favour the evolution of territoriality. Territoriality is the exclusive use of an area (i.e. 'ecological' territoriality) or the active defence of an area from conspecifics using various visual, acoustic, or chemical signals that indicate ownership (i.e. 'behavioural' territoriality; Brown & Orians 1970). Signals advertising ownership may deter intrusions by conspecifics of the same gender or both genders and can also attract opposite-sex conspecifics, which can allow for the monopolization of mates and other limited resources.

Many vertebrate species exhibit either temporary or extended periods of territoriality. Although territoriality implies exclusiveness from conspecifics of the same or opposite gender, the true degree of non-sociality (i.e. avoidance of conspecifics) exhibited by territorial vertebrate species is variable. For example, males of many avian species breeding in temperate climates establish breeding territories but aggregate in large flocks at times outside of the breeding season (Nice 1941). The breeding territories of male songbirds are often defended from male but not female conspecifics, which results in male birds spending a significant portion of each year exclusive of other males. Similarly, females of some small mammal species (e.g. *Microtus*, *Clethrionomys,* and *Peromyscus* spp.) defend nesting territories during the breeding season, but will live in groups of related or unrelated individuals during the non-breeding season (Ostfeld 1990; Wolff 1993). At the other end of the continuum of non-sociality are species that defend year-round territories from both intra- and inter-sexual intruders. For example, both female and male North American red squirrels (*Tamiasciurus hudsonicus*) defend exclusive food-based territories year-round (Smith 1968). Female red squirrels are spontaneous ovulators, and they only appear to allow male intruders on their territories when they are in behavioural oestrous, which is approximately 1 day per year (Smith 1968; Lane *et al.* 2008). Thus, the degree of non-sociality in territorial vertebrate species can range from highly non-social (red squirrels) to tolerance of both sexes for most of the year except during the breeding season (temperate breeding avian species and some small mammal species). There is similar variation in the degree of non-sociality in species that actively defend mates (mate-defence polygyny) rather than actively defending a territory (resource-defence polgyny or monogamy). In mate-defence polygyny (e.g. impala, *Aepyceros melampus*), males typically attack other males during the mating season, but aggregate in large herds with little aggression outside of the mating season (Jarman 1974). Because social interactions can strongly affect the activity of the HPA axis, variation in the degree of non-sociality may interact with stress physiology. Here, we focus on the effects of the social environment on the activity of the HPA axis in vertebrate species that exhibit some degree of non-sociality due to territoriality (Fig. 1).

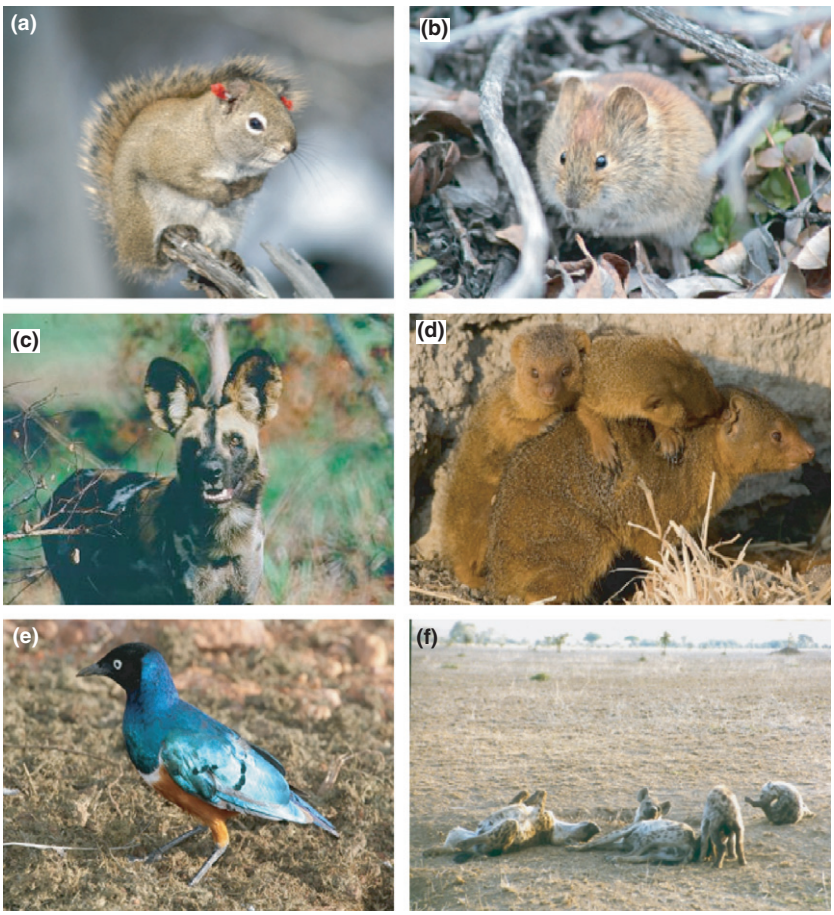

Fig. 1. (a, b) Population density and glucocorticoid levels are usually positively associated in non-social species, although the degree to which territorial vertebrate species are non-social is highly variable. For example, both male and female North American red squirrels (a) defend year-round food-based territories. In other small mammal species such as the northern red-backed voles (b), females only defend nesting territories during the breeding season (photos by R.W. Taylor). In many social species, behavioural dominance is strongly correlated with reproductive success but dominance is also associated with heightened glucocorticoid levels. For example, within groups of African wild dogs (c) and dwarf mongooses (d), only the behaviourally dominant individual of each gender is assured of breeding (photos by S. Creel). However, dominant wild dogs and dwarf mongoose also engage in more aggressive interactions and their glucocorticoid levels are higher than those of subordinates, which may impose fitness costs. In many social species, the relationship between social status and glucocorticoid levels can be complicated by both environmental variation and the method by which social status is acquired and maintained. (e) For example, in cooperatively breeding superb starlings, annual differences in rainfall and resource availability not only influence glucocorticoid levels, but they may do so differently in dominants and subordinates (photo by D. R. Rubenstein). (f) Unlike most other carnivores, social rank in spotted hyenas is inherited from the mother, which complicates the positive relationship between social status and age/size that is seen in many other species (photo by W. Goymann).

FACTORS AFFECTING ACTIVITY OF THE HPA AXIS IN TERRITORIAL SPECIES

In territorial vertebrates, population or breeding density is one of the best documented factors that influence the activity of the HPA axis. Christian (1950) first used Selye's description of stress (or general adaptation syndrome; Selye 1936) to describe how the adrenocortical response to population density might cause the density-dependent population cycles exhibited by some small mammal species. Christian (1950) hypothesized that increases in population density in small mammal species such as voles led to increased antagonistic social interactions, which caused an increase in adrenocortical activity. Christian further predicted that the consequences of this heightened adrenocortical activity were a decrease or suppression of reproduction and an increase in mortality due to decreased resistance to disease or other limiting factors (Christian 1950; Christian & Davis 1964). As a result, population growth ceased or declined during peak population densities due to heightened mortality and decreased fecundity. Christian and colleagues (Christian 1950, 1956, 1961, 1964, 1971; Christian & Davis 1964, 1966) provided extensive empirical documentation in territorial mammalian species of the relationship between adrenal gland mass (a proxy of adrenocortical activity: Bronson & Eleftheriou 1964) and population density and/or the frequency of antagonistic interactions.

Christian's pioneering studies were instrumental in connecting how environmental factors influence the HPA axis

activity of individuals, which in turn affected population dynamics. Groundbreaking studies in a variety of mammalian taxa (primarily rodents) found significant positive relationships between population density and adrenal mass (reviewed by Christian 1971; To & Tamarin 1977) or *in vitro* adrenal secretion of glucocorticoids (Andrews 1968). However, Christian's research has been criticized because it was largely performed on captive animals often in a laboratory setting (Krebs & Myers 1974; Lee & McDonald 1985). Nonetheless, more recent studies in other mammalian species have documented a similar positive relationship between population density and plasma glucocorticoids (Boonstra & Boag 1992; m 1998) or faecal glucocorticoid metabolite concentrations (Novikov & Moshkin 1998; Harper & Austad 2004; Bian *et al*. 2011) in free-living individuals. For example, Boonstra & Boag (1992) found that populations of meadow voles (*Microtus pennsylvanicus*) at the highest densities had the highest free plasma corticosterone concentrations and lowest corticosterone-binding globulin concentrations. Support for this positive relationship between population density and stress axis activity in territorial mammalian species is not universal (e.g. To & Tamarin 1977; Harper & Austad 2004; Kuznetsov *et al*. 2004; Charbonnel *et al*. 2008), and we have little information about the relationship between population density and stress axis activity in some mammalian orders that include many solitary species (e.g. carnivores, of which more than 80% of species are solitary: Gittleman 1984).

The relationship between population density and the activity of the stress axis is best known from studies of mammals. This is not surprising given the initial focus of Christian and colleagues (see above). Although less well-studied than mammals, birds often show similar relationships between density and HPA function. With regard to stress physiology, most of the well-studied avian species breed in temperate regions exhibit territoriality only during the breeding season, and only defend territories from same-gender conspecifics. Although there are fewer studies of birds than mammals, a positive relationship between population density and plasma (Silverin 1998a) or yolk glucocorticoids (Love *et al*. 2008) has been reported for several species, while others have detected no relationship (Beletsky, Orians & Wingfield 1990, 1992). However, further support for the predicted positive relationship between density and stress axis activity in avian species may come from simulated territorial intrusion (STI) experiments. In these experiments, a territorial male is presented with an unfamiliar caged male (or a stuffed male) within his territory, paired with an audio playback of the species' song. Several studies in temperate-breeding birds have found that STIs cause a pronounced increase in plasma glucocorticoids (e.g. Silverin1993, 1998b; Van Duyse *et al*. 2004; Canoine & Gwinner 2005; Landys *et al*. 2007), whereas others have not found such a relationship (e.g. Harding & Follett 1979; Wingfield 1985; Pärn *et al*. 2008; Scriba & Goymann 2010). Because antagonistic interactions and other territorial intrusions are predicted to increase as population density rises (e.g. Bretagnolle, Mougeot & Thibault 2008), we therefore would predict that population density is also positively correlated with stress axis activity in species that responded to STIs with elevated glucocorticoid production. To date, very few studies in avian species that exhibit year-round territoriality have directly tested the relationship between glucocorticoids and population density. However, some studies have found that STIs cause a significant increase in plasma glucocorticoids in bird species exhibiting year-round territoriality (e.g. Gill, Costa & Hau 2008; Landys *et al*. 2010), providing indirect evidence for a positive relationship between population density and stress axis activity.

Other taxa, including amphibians, reptiles and fish, also offer insights into the relationship between population density and HPA function. Amphibians and reptiles often defend resource-based territories and are non-social as adults. Many species only interact with conspecifics during the larval stage or during breeding as adults. Some studies in amphibians and reptiles also support the positive relationship between population or breeding density and stress axis activity. For example, increased population density during mating in anurans (Leary, Garcia & Knapp 2008) or nesting density in turtles (Jessop, Limpus & Whittier 1999) is associated with increased plasma glucocorticoids. High population density either were associated with increased or decreased plasma glucocorticoids in female side-blotched lizards (*Uta stansburiana*) depending upon the female reproductive tactic (Comendant *et al*. 2003). In contrast, experimentally increased densities in breeding salamanders did not elicit elevated plasma glucocorticoids (Cooperman, Reed & Romero 2004). It is important to note, however, that increased glucocorticoid concentrations during breeding aggregations might be driven by changes associated with reproduction that are not related to density (e.g. glucocorticoid concentrations rise during gestation in many mammals; Creel, Winnie & Christianson 2009; Dantzer *et al*. 2010; or glucocorticoid concentrations rise during intense mate competition in marsupials; Bradley, McDonald & Lee 1980; Bradley 1987). Evidence for positive effects of population density on stress axis activity in amphibians and reptiles also comes from laboratory studies. For example, heightened competition over burrows in captive spotted salamanders (*Ambystoma maculatum*; Cooperman, Reed & Romero 2004) or increased housing density in American alligators (*Alligator mississippiensis*; Elsey *et al*. 1990) was associated with increased plasma glucocorticoids (see also Hayes 1997; Glennemeier & Denver 2002). In some lizard species, forced antagonistic interactions with conspecifics in laboratory experiments can elevate plasma glucocorticoids (Klukowski & Nelson 1998; Schuett & Grober 2000; Yang & Wilczynski 2003), which suggests that stress axis activity would be elevated under high density conditions due to a heightened

frequency of antagonistic interactions. In many ways, such studies of forced interaction are similar to early studies of 'social stress' in captive animals that we discuss in the second part of this review.

Finally, it is well established that crowding increases stress axis activity in captive or hatchery reared fish (Barton & Iwama 1991), but we are aware of no studies examining the relationship between population or breeding densities and stress axis activity in free-ranging territorial fish. This is not surprising given the logistical difficulties of such a study. However, future studies in fish species in which males provide paternal care and actively defend brooding sites from conspecifics such as bluegill (*Leopomis macrochirus*; Neff & Knapp 2009) and smallmouth bass (*Micropterus dolomieu*; Hanson *et al*. 2009; Dey *et al*. 2010) should investigate how breeding or nesting density affects stress axis activity.

REMAINING QUESTIONS IN TERRITORIAL SPECIES

In the above section, we have detailed how population or breeding density increases HPA activity in vertebrate taxa and in some cases how forced antagonistic interactions between conspecifics can elevate stress axis activity. However, the positive relationship between population density or the frequency of antagonistic interactions and HPA axis activity is not universal across different taxa. Departures from the general pattern of increased density leading to increased HPA activity could be due to the confounding effects of reproductive condition, seasonality or recent extreme weather events on HPA axis activity or responsiveness (Kenagy & Place 2000; Romero 2002; Romero *et al*. 2008) or to the effects of trapping/handling stress on glucocorticoid levels (Kenagy & Place 2000; Sheriff *et al*. 2011a). As such, future studies examining relationships between population density and HPA axis activity should sample their study animals carefully to avoid these potentially confounding effects.

A central remaining question is to identify if the relationship between population density and HPA axis activity that has been found in many species is due to an increase in antagonistic interactions between conspecifics at high density, decreased per capita food abundance, or even increased attraction of predators. For example, food-abundance often co-varies with population density such that increased overall food abundance is associated with increased reproductive output and/or population density, but perhaps constant or decreased per capita food availability. As a result, determining the actual mechanism that induces heightened HPA axis activity under high population density conditions will require experimental manipulations of the potential causal variables, or careful sampling designs with multiple populations.

Few studies have experimentally manipulated population density, food-abundance or predator densities in free-living non-social territorial animals. In a recent study using a non-social species, the North American red squirrel, population density was positively correlated with faecal cortisol metabolite concentrations (B. Dantzer, unpublished data). Experimental increases in both actual (using long-term food supplementation) and perceived population density (using audio playbacks of territorial vocalizations to simulate high density conditions) also caused a significant increase in faecal corticosteroid metabolites (Dantzer *et al*. unpublished data). This suggests that, at least in this species, the actual variable causing changes in glucocorticoids (and also density-dependent behavioural responses; Dantzer *et al*. in press) is the perception of social competition and not food abundance or predator densities.

In addition to population density, predation risk may affect HPA axis activity in territorial species. For example, predator density affects plasma free glucocorticoid concentrations in snowshoe hares (*Lepus americanus*) (Boonstra *et al*. 1998; Sheriff, Krebs & Boonstra 2011b) and total plasma glucocorticoid concentrations in African stonechats (Scheuerlein, Van't Hof & Gwinner 2001). In elk, (*Cervus elaphus;* Creel, Winnie & Christianson 2009), predator density did not detectably affect faecal corticosteroid metabolites concentrations, although progesterone concentrations and calf production did decline in response to predation risk (Creel *et al*. 2007). To date, too few studies have examined the relationship between HPA activity and predation risk to infer general relationships with confidence. However, recently Zanette *et al*. (2011) simulated a strong increase in the perceived risk of predation using predator vocalization playbacks and observed behavioural changes in territorial female song sparrows, associated with a nearly 40% reduction in clutch size at fledgling. The impact of predation pressure in natural situations may be more subtle than in this experiment, because it simulated a situation with severe predation pressure by broadcasting predator vocalizations steadily for 130 days on a 4 day on/off basis (Zanette *et al*. 2011). This reduction in clutch size may be through a stress-mediated pathway because previous studies have found that glucocorticoids were elevated in response to increased predator abundance (Clinchy *et al*. 2004, 2011). This study experimentally confirms observational studies that have shown strong effects of predation risk on individual reproduction in wild populations, although these are not necessarily stress-mediated (Creel *et al*. 2007). We suggest that future studies examining relationships between population density and the activity of the stress axis should also consider how food abundance and predation risk co-vary with population density and HPA activity (see also McColl 1998).

As with studies of social species (see below), broader assessments of HPA function and tests for fitness effects in non-social species remain important. Although the initial focus of Christian and colleagues was to examine how population density or environmental variation influences the population dynamics of non-social animals through HPA axis activity, no studies that we are aware of have actually explored how HPA axis activity of individuals affects population dynamics as the focus of most field

studies to date has been on *individuals*. While it is reasonable to assume that effects on individual fitness often have consequences for population dynamics, it will be productive to return to the ideas of Christian and explore how the glucocorticoid responses of individuals to environmental variation can influence population or even community dynamics (Hawlena & Schmitz 2010). This will require careful experimentation of population densities and even HPA axis activity with tractable study species to examine if the glucocorticoid responses of individuals to environmental variation affect population density.

Effect of the social environment on the stress axis in group-living vertebrates

SOCIAL SPECIES: SOCIAL STATUS AND DOMINANCE RANK

Animals living in social groups often form dominance hierarchies. An individual's position within the dominance hierarchy can have strong effects on fitness, because social dominance often confers priority of access to mates, food and other resources (Fig. 1). In many cooperatively breeding birds and mammals, the probability of breeding is almost one for the socially dominant individual of each gender and almost zero for social subordinates. Given these clear benefits of social dominance, many early studies of aggression, rank and physiological stress responses were based on the hypothesis that low social status is stressful. Early research on captive rodents and primates supported this hypothesis (Bronson & Eleftheriou 1964; Louch & Higginbotham 1967; Manogue, Leshner & Candland 1975). In paired contests between laboratory rats, mice and monkeys, aggression increased glucocorticoid secretion in both winners and losers, but the effect was significantly stronger among losers. Thus, as field studies began to examine stress responses in the wild in the 1980s, a plausible hypothesis was that the 'stress of subordination' might underlie the reproductive suppression of social subordinates in many cooperatively breeding species.

However, social hierarchies and agonistic behaviour evolve to avoid the costs of overt aggression. This general explanation for the evolution of agonistic behaviour is predicated on the assumption that contests among group members can carry costs (Rubenstein & Shen 2009). The costs of engaging in agonistic or aggressive interactions (and more generally the costs of a given social position) are often not equal for both of the individuals involved, and this observation raises an interesting range of possibilities. If winning a direct contest provokes a weaker stress response than losing, but dominant individuals engage in more contests, then the total effect may be that dominants have higher mean circulating glucocorticoid levels than subordinates. In addition to direct contests, it is plausible that the maintenance of high rank requires more monitoring or 'policing' of the behaviour of others than is required for animals with low rank, simply due to differences in the number of group mates who are subordinate to individuals of different rank. Observations of wild groups commonly show that dominant animals do engage in higher rates of aggressive and agonistic behaviour in many species (e.g. most social carnivores: Creel *et al*. 1997; Sands & Creel 2004), so it is plausible to hypothesize that social stress is greater for dominants than for subordinates, but the fitness costs are offset by the other benefits of high rank.

Given that one might plausibly hypothesize either positive or negative correlations between social status and glucocorticoid secretion, empirical data from wild populations are necessary to advance the science. Robert Sapolsky, one of the pioneers of social stress research in free-living animals, found that subordinate male olive baboons (*Papio anubis*) are more likely to be physiologically stressed than dominants and show chronically elevated levels of glucocorticoids (Sapolsky 1982, 1983). As a consequence of chronically elevated glucocorticoids, subordinate baboons are more likely to develop stress-related pathologies than dominants (Sapolsky, Alberts & Altmann 1997; Sapolsky & Spencer 1997). In follow-up studies, Sapolsky and coworkers discovered that this rank-related pattern in glucocorticoid physiology may be modified by styles of dominance (Ray & Sapolsky 1992), or may be suspended by environmental impacts, such as during a severe drought during which all members of the social group devoted most of their time to foraging, leaving little opportunity for social harassment (Sapolsky 1986). Most notably, Sapolsky (1992a) suggested that the relationship of glucocorticoid concentrations to rank depended on the stability or instability of baboon hierarchies. In stable hierarchies, the glucocorticoid levels of subordinates were higher than the glucocorticoid levels of high-ranking baboons, but this pattern was reversed during periods of social instability. Sapolsky's early results from free-ranging baboons supported the prevailing view from laboratory studies (e.g. Manogue, Leshner & Candland 1975) that subordinates are generally more likely to suffer from social stress than dominants. More importantly, these studies highlighted the role that social stability has on glucocorticoid levels in some species.

With the availability of non-invasive methods to measure hormone metabolites from urine or faeces, studies on the relationship between social rank and glucocorticoid levels of free-living animals have become more common over the past two decades. Some of these studies challenged the traditional view of the relationship between glucocorticoids and social rank in free-living animals that subordinates tend to have higher levels than dominants, arguing instead that dominants experience more psychosocial stress and often express higher levels of glucocorticoids than subordinates (Creel 2001). For example, glucocorticoid levels were higher in dominants than in subordinates in free-living African wild dogs (*Lycaon pictus*) and dwarf mongoose (*Helogale parvula*) (Creel, Creel & Monfort 1996; Creel *et al*. 1997). Both species are cooperative breeders and live in groups with '*despotic hierarchies*'

(Sapolsky 2005). Similarly, in cooperatively breeding African cichlid fish (*Neolamprologus pulcher*) dominants had higher glucocorticoid levels than subordinates (Mileva, Gilmour & Balshine 2010). The same pattern has been reported for several wild populations of cooperatively breeding primates (reviewed in Creel 2001) and gray wolves (*Canis lupus*; Sands & Creel 2004). In cooperatively breeding birds, dominants and subordinates often show similar glucocorticoid levels (e.g. Schoech, Mumme & Moore 1991; Wingfield, Hegner & Lewis 1991; Mays, Vleck & Dawson 1991; Malueg, Walters & Moore 2009). Together, these studies demonstrate that social rank has important effects on glucocorticoids in social species, but that the patterns differ among taxa and may vary with the stability and type of dominance hierarchy. Even in closely related pairs of species, pronounced differences have been observed. For example, dominant dwarf mongooses largely monopolize reproduction (Creel & Waser 1991; Creel *et al.* 1992), although dominant individuals have higher mean glucocorticoid levels than subordinates. When subordinate females do breed, their offspring are often killed, but social interactions with the breeding subordinate do not detectably change. In contrast, glucocorticoid levels are higher in subordinate females of alpine marmots (*Marmota marmota*), which are frequently attacked by dominant females (Hackländer, Möstl & Arnold 2003) and slender meerkats (*Suricata surricata*), who are subject to violent eviction from their group if they become pregnant (Young *et al.* 2006). Sapolsky (2005) reviewed the conditions under which social stress is stronger for dominants or stronger for subordinates and suggested several social conditions or individual traits that promote differences in social status related glucocorticoid patterns (resource inequity, maintenance of dominance, breeding style, stability of social ranks, subordinate coping strategies, subordinate avoiding mechanisms of dominants, subordinates' use of alternative strategies, stress of dominating mating, atmosphere of culture and personality). While much has been learned, further work is needed to fully disentangle the relationships between glucocorticoid secretion, social status and the behavioural causes and consequences of rank in social vertebrates (Creel 2001; Goymann & Wingfield 2004; Sapolsky 2005; Rubenstein & Shen 2009).

Social status and social interactions can be described in many ways. Some studies treat social status as a dichotomy, pooling subordinates into one category and comparing them to the top-ranked (alpha) individual in each group. Other methods produce a rank-order, treating social status as an ordinal variable. Still other methods consider quantitative variation, treating rank as a continuous variable. Most studies to date have tested for a categorical difference in the glucocorticoid levels of alphas and subordinates, or for a linear relationship between glucocorticoid levels and rank. Empirical research is just beginning to evaluate the possibility that glucocorticoid secretion may relate to social rank in a more complex manner. A recent, long-term study of savannah baboons (*Papio cynocephalus*) illustrates this point well. Although the highest-ranking (alpha) males had elevated glucocorticoid levels, high-ranking males other than alphas tended to have lower glucocorticoid levels than low-ranking males (Gesquiere *et al.* 2011). Studies of other species have also reported that the glucocorticoid levels of alphas are elevated, with no detectable relationship between rank and glucocorticoids among non-alphas (e.g. in Yellowstone wolves; Sands & Creel 2004). Still other studies have found that the endocrine profiles of alphas and betas (second-ranked) animals are similar, with little relationship among lower ranks (for example in African wild dogs; Creel *et al.* 1997). Interestingly, the patterns that Gesquiere *et al.* (2011) observed for baboons were not affected by the stability or instability of the hierarchy, in contrast to the results of Sapolsky (1992a) for the same species.

LIVING IN SOCIAL GROUPS MAY REDUCE STRESS

An important, but often neglected, aspect in the discussion of the effect of the social environment on stress physiology is that the social environment may not only produce stress, but in fact it may reduce overall stress levels. For example, social support may buffer glucocorticoid levels in baboons (Alberts, Sapolsky & Altmann 1992; Ray & Sapolsky 1992; Virgin & Sapolsky 1997) and in greylag geese (*Anser anser*), the size of the family unit led to a decrease in the stress response during competitive feeding situations with other flock members (Scheiber *et al.* 2005; Scheiber, Kotrschal & Weiss 2009; see also a review on social buffering of the HPA-axis by Hennessy, Kaiser & Sachser 2009).

HOW SOCIAL STATUS IS ACQUIRED AND MAINTAINED MAY AFFECT THE RELATIONSHIP BETWEEN SOCIAL STATUS AND GLUCOCORTICOIDS

It is often assumed that success in aggressive interactions and the achievement of high dominance status are always a function of morphological and physiological characteristics. However, it has now become clear that social rank means different things in different species or even populations of the same species. Rank as a descriptor of social status does not specify the process by which social roles are obtained or maintained. Thus, behavioural strategies related to the acquisition and maintenance of rank, rather than the rank *per se*, are likely to determine the degree of social stress (and glucocorticoid levels) associated with a particular social status (von Holst 1998; Creel 2001; Goymann *et al.* 2001, 2003; Abbott *et al.* 2003; Goymann & Wingfield 2004; Sapolsky 2005).

In groups where dominance rank is inherited or dominance is achieved via queuing conventions social status is unlikely to have a major effect on glucocorticoid levels,

as long as there are no acute challenges (Goymann & Wingfield 2004; Sapolsky 2005). A similar scenario may occur in many 'high skew' cooperatively breeding species where a single dominant pair breeds and the other group members assist rearing the offspring (Vehrencamp 1984; Keller & Reeve 2004). In some species (e.g. many cooperatively breeding birds), adult subordinates are mainly offspring from prior years (e.g. Brown 1978). In other species, group structures are more complex and subordinates encompass a wide range of ages and degrees of genetic relatedness, including immigrants from other groups (e.g. in African wild dogs; Creel & Creel 2002). In cooperatively breeding species with high skew in reproductive success, reproductive suppression is experienced by most group members at some stage of their lives, and many individuals remain socially subordinate for their entire lives. Neuroendocrine mechanisms that operate mainly within the hypothalamic-pituitary-gondal axis are the prime mediators of reproductive suppression and glucocorticoid levels play only a minor role (e.g. Faulkes & Abbott 1997; Saltzman, Digby & Abbott 2009). Hence, similar to species with rank-inheritance or queuing conventions, rank-related patterns of glucocorticoid levels are unlikely to be the cause of reproductive suppression, and as long as there are no acute challenges, the correlation between rank and glucocorticoids could be positive, negative or neutral (Creel, Creel & Monfort 1996; Goymann & Wingfield 2004; Sapolsky 2005).

In contrast to stable social societies where rank is inherited or reproductive suppression is common, when there is conflict about reproduction in cooperative species, rank-related patterns of glucocorticoids may arise. For example, dominant pregnant female meerkats (*Suricata suricata*) aggressively target older and more distantly related subordinate females that represent a threat to their own reproduction. These subordinates show an impaired function of the hypothalamic pituitary gonadal axis, which may be caused by chronic elevation of glucocorticoid levels (Young *et al.* 2006). A similar situation occurs in many plural breeding species (where there are normally multiple breeding individuals within the group). Here, reproductive options exist for more than one breeding pair in a group and social dominance is acquired and maintained with low level or overt aggression, and subordinates are frequently threatened by dominants. Here, a social status related pattern of acute and chronic elevation of glucocorticoid levels is commonly observed in subordinates (Abbott *et al.* 2003; Goymann & Wingfield 2004; Sapolsky 2005). Such patterns are more likely to occur in societies with strong group cohesion as opposed to fission-fusion groups (Goymann & Wingfield 2004; Sapolsky 2005). In summary, current research suggests that it may not be the dominant or subordinate position itself, but rather the process by which social status is acquired and maintained that determines the physiological and psychosocial effects associated with a given social status (Sapolsky 1992b; Abbott *et al.* 2003; Goymann & Wingfield 2004).

INTERACTIONS BETWEEN SOCIAL AND ENVIRONMENTAL FACTORS

Social living is strongly influenced by ecological and environmental factors. In particular, resource distribution in time and/or space drives dispersal decisions, movement patterns and patterns of association in many taxa (Jarman 1974; Emlen & Oring 1977; Rubenstein & Lovette 2007; Jetz & Rubenstein 2010). These same ecological and environments factors also affect glucocorticoid levels in social species. In cooperatively breeding superb starlings (*Lamprotornis superbus*) (Fig. 1), annual differences in rainfall and resource availability not only influence glucocorticoid levels, but they may do so differently in dominant and subordinate individuals (Rubenstein 2007). However, these rank-related differences in glucocorticoid patterns may be more related to environmentally driven differences in levels of social conflict than to environmental factors directly (Rubenstein & Shen 2009). Similarly, in ring-tailed lemurs (*Lemur catta*), where social stressors and rank influenced glucocorticoid levels in captivity (Starling *et al.* 2010), socially-mediated glucocorticoid levels were also differentially impacted by food availability and environmental stress in the wild (Pride 2005). Although glucocorticoid levels are strongly influenced by social rank in savannah baboons (Gesquiere *et al.* 2011), environmental stressors also had strong effects on the patterns (Gesquiere *et al.* 2008). Thus, while social factors like rank and dominance interactions shape glucocorticoid levels in many species of birds and mammals, environmental factors like resource availability often interact with social factors to shape hormone profiles. One of the future goals in comparative studies of stress physiology in social species should be to disentangle the effects of social and environmental factors on hormone levels and social roles. So far, few studies have experimentally altered social (population density) or environmental factors (predator densities or food-abundance) in social species and investigated the consequences on demography, reproductive success and glucocorticoid secretion For example, food supplementation increased reproductive success in Florida scrub jays (*Aphelocoma coerulescens*). Breeding females supplemented with food started to reproduce earlier, laid larger clutches, and the survival of their offspring was increased (Schoech *et al.* 2008). Glucocorticoids possibly play a role in the mediation of this enhanced reproductive success, as jays supplemented with a high fat and high protein diet had lower glucocorticoid levels than controls and jays supplemented with a diet high in fats but low in proteins (Schoech, Bowman & Reynolds 2004; Schoech 2009). As a consequence, food supplementation may increase local population densities of this threatened species perhaps by lowering glucocorticoid levels and enhancing reproduction.

ALLOSTASIS, SOCIAL STATUS AND GLUCOCORTICOIDS

Separating the effects of social and ecological factors on glucocorticoid levels in free-living social animals may be difficult. The theoretical framework of allostasis has been proposed to help simultaneously study the effect of social and ecological factors on glucocorticoid levels in group-living species (Goymann & Wingfield 2004; Rubenstein & Shen 2009). Allostasis is a controversial theory that emerged from the biomedical literature (McEwen & Wingfield 2003) and has been applied more broadly to other biological disciplines, including studies of vertebrate social behaviour (Goymann & Wingfield 2004; Rubenstein 2007; Rubenstein & Shen 2009; Saltzman, Digby & Abbott 2009). Allostasis, which means achieving internal stability through bodily change of state, supports homeostasis by adjusting set-points to unpredictable stressors away from homeostatic baselines (Sterling & Eyer 1988). McEwen & Wingfield (2003) have used this allostasis framework to describe the physiological costs of coping with social and environmental challenges, and how physiological mediators such as glucocorticoids regulate responses (McEwen & Wingfield 2003). The allostasis framework has been extended by Romero, Dickens & Cyr (2009) in the reactive scope model to build from the allostasis model and address some of its criticisms. Together these models provide a starting place for exploring how predictable and unpredictable social and environmental stressors influence physiology and behaviour in social species.

Models of allostasis treat social interactions as a type of unpredictable social stressor (McEwen & Wingfield 2003; Goymann & Wingfield 2004; Romero, Dickens & Cyr 2009; Rubenstein & Shen 2009). Laboratory experiments have shown that unpredictable or uncontrollable stressors (such as electric shocks) provoke stronger glucocorticoid responses than the same stimuli when they are predictable or controllable (e.g. Weiss 1970). Although it is obvious that intense, short-term stressors like storms are unpredictable challenges that organisms cannot anticipate, many types of social interactions may also be relatively unpredictable. Animals that live in groups will experience affiliative social interactions daily (e.g. foraging, grooming, sleeping), and although these interactions may increase seasonally, they are still generally predictable events because animals can largely anticipate their occurrence. However, for social animals living within a dominance hierarchy that defines reproductive roles, changes in social status are often triggered by violent, escalated aggression. These escalated fights might be less predictable (although they are more likely under certain circumstances, such as the annual breeding period: Creel & Creel 2002; Young *et al.* 2006). In response to such interactions, an individual will rapidly shift its level of glucocorticoids to a new optimum in order to cope with the stressor. Thus, an acute social conflict might be analogous to a somewhat unpredictable environmental challenge (McEwen & Wingfield 2003; Goymann & Wingfield 2004; Romero, Dickens & Cyr 2009).

Allostasis models also specifically address the idea we described above that the physiological and psychosocial effects associated with a given social status are the result of the process by which social status is acquired and maintained rather than the resulting dominance rank *per se*. The process of rank acquisition is reflected in the level of allostatic load, or the cumulative physiological burden exacted on the body, as individuals adjust behaviour to aggressive social interactions (Goymann & Wingfield 2004). Allostatic load can be reflected in glucocorticoid levels (McEwen & Wingfield 2003; Goymann & Wingfield 2004; Rubenstein & Shen 2009). A comparative study by Goymann & Wingfield (2004) demonstrated that across a large sample of social bird and mammal species, the relative levels of glucocorticoids in dominants and subordinates are related to allostatic load and the way that rank is achieved and maintained in different societies. This work was extended theoretically and empirically by Rubenstein & Shen (2009) to predict the environmental conditions under which dominants or subordinates are expected to have higher allostatic load. This work also demonstrated that group structure (i.e. the ratio of breeders to non-breeders in a group) could also influence allostatic load and relative glucocorticoid levels. Together, these studies suggest that the allostatic load framework may help explain not only the different rank-related patterns seen in glucocorticoid patterns in vertebrates, but also the environmentally driven intra-specific variation in levels seen across years in long-term studies of individual species. The allostasis framework may also prove fruitful in studying the effects of factors on stress physiology in social species, such as the role of ontogeny and maternal effects during development.

SOCIAL ENVIRONMENT DURING ONTOGENY: PRENATAL AND POSTNATAL DEVELOPMENT

The effect that the social environment may have during the ontogeny of animals has received little attention in studies of free-living social species. The hormonal stress-axis of the mother and the offspring during early life may play a role in shaping the expression of phenotypic traits. Phenotypic plasticity, or the ability of an individual organism to alter its phenotype in response to changes in environmental conditions (Stearns 1989; Garland & Kelly 2006), is relatively understudied at both the functional and mechanistic levels in social species. In social species, individuals may adapt their phenotype to the social conditions encountered during ontogeny. A variety of laboratory studies have demonstrated that stressors acting on the mother during pregnancy or lactation (or during oogenesis in birds) may result in long-lasting effects on the offspring (reviewed in de Kloet *et al.* 2005; Catalani *et al.* 2011; Henriksen, Rettenbacher & Groothuis 2011). Whereas the mammalian literature generally takes a biomedical

perspective with the prevailing view that environmental stressors lead to pathologies, or deviations from the norm, the avian literature typically takes a more evolutionary perspective (Groothuis *et al.* 2005), with the prevailing view that environmental influences during early ontogeny (e.g. maternal effects) may help offspring to adapt to the current environment (Henriksen, Rettenbacher & Groothuis 2011). In captive animals, such as guinea pigs (Kemme, Kaiser & Sachser 2007, 2008), manipulations of the stability of social groups had no effect on HPA activity. Interestingly, however, male guinea pigs whose mothers lived in an unstable social environment during pregnancy and lactation had higher levels of testosterone later in life compared to males whose mothers lived in a stable social environment during this period. A study in spotted hyenas (Fig. 1) found that androgen metabolite levels are higher in dominant female spotted hyenas during pregnancy, which may affect offspring aggression (Dloniak, French & Holekamp 2006). However, the observed effect on aggressive behaviour was small, and potential effects on the HPA axis of the offspring were not investigated. A study of adoption in free-living spotted hyenas found that the influence of the social status of the surrogate mother on offspring behaviour was much stronger than the effects of the prenatal hormonal environment (East *et al.* 2009). In birds, development occurs in both the egg and during the nest stage (when direct hormonal effects from the mother are unlikely to occur). In cooperatively breeding Florida scrub-jays, parental provisioning rates directly influence baseline glucocorticoid levels in nestling (Rensel, Boughten & Schoech 2010b). The stress response in this species varies in different developmental stages (Rensel, Wilcoxen & Schoech 2010a) and is quite repeatable across different developmental periods (Rensel & Schoech 2011). Therefore, early life and developmental experiences in the nest may influence stress-physiology throughout adulthood.

Developmental effects on stress physiology in social species may not just be limited to circulating hormone levels. In studies of laboratory rats, variation in maternal care altered the expression of genes that regulate behavioural and hormonal stress responses, forming the basis of consistent individual differences in stress reactivity (Meaney *et al.* 1996; Meaney 2001). Similar programming may occur during adolescence. In guinea pigs, housing conditions from early adolescence through adulthood had profound effects on behaviour and hormone physiology of males: males that spent the adolescence period in mixed gender colonies showed a reduction in stress responsiveness compared to males that were housed with a single female during adolescence (Kaiser *et al.* 2007; Lürzel, Kaiser & Sachser 2010). It is unclear if these laboratory studies can be generalized to free-living animals, but it is possible that this kind of programming of the offspring stress responsiveness may be adaptive. For example, the social status of the mother, the stability of the social hierarchy she lives in, or the amount of alloparental care provided by helpers could influence offspring provisioning and/or care. This variation in offspring care may then transduce a social status related signal to the offspring, which could in turn, programme the offspring's reactivity to environmental stressors. Rank-related differences in maternal care that may potentially lead to such programming are known from wild populations (Pusey, Williams & Goodall 1987), and in wild baboons, persistent effects of female rank on offspring HPA activity have been demonstrated (Onyango *et al.* 2008). In summary, laboratory studies suggest that the social environment during embryonic development, in the nursing or nestling phase, and during adolescence may programme the hormonal stress response. Because it is currently unclear whether such programming may affect fitness or what consequences this programming may have on population demography, studies of free-living animals are needed to answer these questions.

Future directions

LINKING HPA FUNCTION AND FITNESS IN THE WILD

For both social and non-social species, much of our interest in relationships between social or environmental conditions and glucocorticoid concentrations is motivated by a desire to understand the physiological mechanisms by which the environment affects fitness. However, it is difficult to establish causal relationships between glucocorticoid levels and social behaviour or environmental conditions. Likewise, understanding the relationship between glucocorticoids and fitness is not straight-forward. Prolonged elevated baseline levels of glucocorticoids are commonly viewed to be detrimental, costly and decrease fitness (Sapolsky, Romero & Munck 2000). However, there is little consistent evidence for a negative association between elevated baseline glucocorticoids and fitness (Bonier *et al.* 2009a). Part of the variation among species in the glucocorticoid/fitness relationship could be attributed to a variety of demographic, social (e.g. social rank, age, group size) or environmental factors (e.g. resource availability). Additionally, seasonal patterns of glucocorticoid release could also obscure the relationship. For example, many of the studies of HPA-fitness relationships reviewed by Bonier *et al.* (2009a,b) were conducted in the breeding season. Although many species show elevated baseline levels of glucocorticoids during breeding (Romero 2002), this does not necessarily indicate that these breeders are chronically stressed. Rather, elevated levels of glucocorticoids during breeding may play a role in the regulation of enhanced metabolic needs during reproduction. During breeding, elevated baseline levels of glucocorticoids may actually be predictive for high reproductive success in some species (Bonier *et al.* 2009b; Ouyang *et al.* 2011). Just as the accumulation of studies across a range of species and conditions altered our understanding of relationship between HPA function and rank, we suggest that studying the relationship between HPA function and fitness across a range

of species and conditions will yield new insights. Studies along ecological or social gradients (e.g. variation in population density or variation in group size) will be of particular value.

HYPOTHALAMIC-PITUITARY-ADRENAL FUNCTION AT MULTIPLE LEVELS

In addition to looking at glucocorticoids in different life history stages, it may also be important to look at other components of the HPA-axis. Studies that incorporate a range of methods [baseline glucocorticoid measurements, glucocorticoid responses to acute stressors, adrenocorticotropic hormone (ACTH) challenge and dexamethasone suppression] will be of particular value. For example, baseline and maximal stress-induced glucocorticoid levels bind to different types of receptors (Romero 2004) and may have fundamentally different effects on behaviour. In cooperatively breeding, superb starlings, baseline, maximal levels and stress responses tended to show similar patterns in individuals of different social rank (Rubenstein 2007), but the same may not be true in all species. What may be most relevant to understanding the relationship between glucocorticoids and fitness in social species is the response to stress and the feedback regulation of glucocorticoid release (reviewed in Romero 2004), which has been demonstrated for baboons (Sapolsky & Altmann 1991; reviewed in Sapolsky, Romero & Munck 2000; Sapolsky 2002). Although dominant baboons typically expressed lower baseline glucocorticoid levels than subordinates, when faced with a stressor, glucocorticoid levels not only increase much faster in dominants than in subordinates, but dominants also terminated the release of glucocorticoids more quickly after cessation of the stressful event (Sapolsky & Altmann 1991; Sapolsky 1993). These differences between dominants and subordinates were neurally driven and could not have been elucidated simply with studies of circulating hormones levels. When injected with corticotropin-releasing factor (CRF), the hypothalamic peptide that induces release of ACTH from the anterior pituitary, dominants responded with a larger increase in ACTH than subordinates, which then led to a much faster increase in glucocorticoid production. Shutting down the adrenocortical stress response via negative feedback was more efficient in dominants. Sapolsky demonstrated this by administering dexamethasone, a synthetic glucocorticoid that artificially stimulates negative feedback of the HPA axis (Sapolsky & Altmann 1991; Sapolsky 1993). To our knowledge, these data are the only ones relating negative feedback regulation of the HPA-axis with fitness and social status in a free-living vertebrate. Data from marine iguanas (*Amblyrhynchus cristatus*) suggest that individuals with an effective negative feedback regulation were more likely to survive a severe environmental stressor than individuals with a less effective negative feedback regulation (Romero & Wikelski 2010). Thus, for baboons and marine iguanas, the effectiveness of negative feedback regulation of the HPA-axis can be a predictor of fitness. These studies demonstrate that field studies can examine not only circulating glucocorticoid levels, but also feedback mechanisms. Broad inferences will not be possible until more studies have been performed, because HPA sensitivity can vary with age, and despite their generally inhibitory effects on CRF, glucocorticoids can have locally positive feedbacks on CRF release (e.g. in the central amygdala, which is involved in social behaviour: Schulkin, Morgan & Rosen 2005).

Conclusion

In summary, the increase in the number of studies of glucocorticoids in free-living vertebrates in the past two decades has greatly influenced our understanding of stress physiology. However, many exciting avenues for future research exist. More complete descriptions of HPA function and a better understanding of the complex relationships between glucocorticoids and fitness will be fundamental. Determining these relationships will require long-term studies of organisms with known ages in different life history stages and demographic, social and environmental contexts, as well as comparisons among populations or experimental manipulations of the putative causal variables that affect HPA axis activity. Maternal and organizational effects on neuroendocrine and epigenetic components of stress physiology in free-living animals are also areas ripe for exploration. To achieve these and other goals, we must move beyond simply assaying plasma glucocorticoid or faecal glucocorticoid metabolite levels. Studies should simultaneously examine natural and experimentally induced stress responses and the associated negative feedbacks. Moreover, studies of glucocorticoid receptors and binding globulins are mostly lacking in field studies and would help to fully understand the complexities of stress physiology. Much of what we know about stress comes originally from the biomedical literature. For several decades, extending concepts from biomedical research to studies in the wild has been a productive way to learn how individuals respond to unpredictable social and environmental challenges, and how these responses influence fitness or population demography. While much has been learned, well-identified avenues for future research remain.
